## PHYSICIANS NEEDED IMMEDIATELY FOR THE ARMED FORCES

Under the heading of Medicine and the War in this issue of THE JOURNAL appears an official statement by General Hershey, director of the Selective Service System, relative to the recruitment of physicians for the United States Army Medical Corps. This statement, addressed to the state directors of the Selective Service System, discusses the new plan, already described in THE JOURNAL, whereby teams for the recruitment of physicians are established in the various states. Following a meeting in Omaha on May 8 the plan was extended also to all states west of the Mississippi River. In each state representatives of the Office of the Surgeon General of the Army, of the Adjutant General's Office and the state representative of the Procurement and Assignment Service for Physicians, Dentists and Veterinarians will function as a team for the recruitment of physicians. They have authority to issue commissions in the grades of lieutenant and captain, immediately following physical examination. This step has been necessary because of the shortage now prevailing of five thousand physicians for the U S Army Medical Corps. No doubt physicians in more than adequate numbers will respond.

Never has there been any question of the patriotism of the medical profession! Any delay that has occurred up to now in enrolment has been associated with the desire of every physician to serve in the capacity for which he is best suited. The various techniques that have been developed for making such determination have apparently resulted in some delay by physicians in making themselves available prior to receipt of the enrolment form and questionnaire now in the hands of every physician. Already many thousands of these enrolment forms have been received in the office of the National Roster. The names of physicians who

select Army as first choice will no doubt soon be supplied to the state recruitment teams, they may then call on such physicians for immediate action. However, physicians must not wait for such call, they are needed now. They may apply for immediate commissioning to the state representatives of the Procurement and Assignment Service.

The circular issued by General Hershey calls particularly to the attention of the local boards of the Selective Service System the type of consideration to be given to claims by physicians for deferment because of dependency. Physicians who are commissioned as officers will, of course, have much more difficulty in sustaining a claim based on dependency than would those who are enlisted in ranks below that of lieutenant or captain.

As experience has developed, it becomes more and more apparent that many of the difficult problems associated with the recruitment of physicians are being solved. By a decision now prevailing, physicians who are not citizens may enlist in the United States Army and after three months of service may be made citizens. If the situation concerns a physician from abroad who is licensed to practice in one of the states, he may become a citizen by enlisting in the United States Army and after a period of three months may become a citizen and apply for a commission.

Today the situation is much more complicated than in the times of previous wars. A system of extended residencies and assistantships associated with qualification for the certificates of the boards in the various specialties now covers many young graduates in medicine. Especially needed at this time as a means of encouragement to such young men in offering their services to the armed forces is a definite action on the part of each one of the certifying boards indicating the extent to which it will accept military service as a part of the requirement for certification in a specialty of medical practice.

A meeting of the Committee on Medical Preparedness of the American Medical Association was held in Chicago on May 9. The Committee on Medical Preparedness considered many of the problems which now confront the medical profession in relation to an adequate supply of medical officers for the armed forces. The headquarters of the American Medical Association is giving its fullest cooperation to the Surgeon General and to the Office of Procurement and Assignment. The American medical profession has never failed in its response to the government of the United States when its members were needed in time of war.

## HISTOPLASMOSIS

Stimulated by the statements of Manson and Ross that kala azar probably existed in America, Samuel T. Darling began the search for Leishman-Donovan bodies in smears from the spleen, liver and bone marrow in all cases of splenomegaly that were examined post mortem at Ancon Hospital, Canal Zone, Panama. In 1905 Darling<sup>1</sup> encountered a patient with splenomegaly, emaciation, irregular fever, leukemia and anemia. The essential pathologic features found post mortem on this patient were "the invasion of endothelial cells in the smaller lymph and blood vessels and capillaries by enormous numbers of a small encapsulated micro-organism causing necrosis of the liver, with cirrhosis, splenomegaly, pseudogranulomas of the lungs, small and large intestines with ulceration of the latter, and necrosis of lymph nodes draining the infected viscera." The organism was round to oval and measured from 1 to 4 microns in diameter. After staining, the organism was seen to possess a refractile achromatic rim within which occurred a polymorphous chromatin nucleus, basophilic cytoplasm and achromatic spaces. The similarity to the Leishman-Donovan body of kala azar was striking. The organism differed, however, from the latter in the form and arrangement of its chromatin nucleus and in not possessing a blepharoplast. Darling regarded this as a protozoan parasite, he called it *Histoplasma capsulatum* and the disease produced by it histoplasmosis. Two additional cases were seen within the next nine months.

Reilly and Watson reported in 1926 from Minnesota the first case of histoplasmosis to be recorded in the United States. In 1928 Crumrine and Kessel reported a case from California. In 1934 Dodd and Tompkins<sup>2</sup> of Vanderbilt University School of Medicine reported a case occurring in a 6 month old infant born in Tennessee. This was the sixth case to be recorded in literature and the first to be diagnosed during life. Tompkins found the yeastlike parasite within large mononuclear cells in films of the peripheral blood stained by supravital methods. At the necropsy, material was obtained from which *Histoplasma capsulatum* was successfully cultivated by DeMonbreun of the Department of Pathology of the same school. DeMonbreun<sup>3</sup> succeeded in cultivating the invading organism both in the yeastlike form as it appears in the lesions and as a mycelium. The pathogenic phase of the fungus is the yeastlike form. DeMonbreun further succeeded in reproducing the disease in 2 monkeys by intravenous injection of 5 cc. of a broth suspension of a three day

culture from a blood agar slant. Three days before the animal died the parasites were found in large numbers within the mononuclear cells in smears of the peripheral blood. Necropsies revealed in each case enlargement of the spleen, liver and lymph nodes. Smears from these organisms and from the bone marrow showed enormous numbers of the intracellular parasites. The parasites were recovered in cultures of the tissues. The fungus thus complied with all of Koch's postulates and is therefore to be regarded as the etiologic agent in the 6 cases reported.

Meleney,<sup>4</sup> in a comprehensive review published in 1940, collected 19 reports of cases and 13 additional cases which have come to his attention but have not yet been reported. He calls attention to the fact that histoplasmosis or reticuloendothelial cytomycosis appears commonly as a systemic febrile disease similar to kala azar with a large liver and spleen, a septic temperature, anemia and leukopenia. In other cases lymph node enlargement may predominate simulating Hodgkin's disease, leukemia, lymphosarcoma or aplastic anemia. In still another group pulmonary symptoms may predominate, and infection is often complicated or superimposed on pulmonary or general tuberculosis. Pathologic alterations consist of an enlarged spleen and gray or white nodules in the lungs, liver, spleen, the intestine and the pulmonary and peritoneal surfaces. Henderson, Pinkerton and Moore<sup>5</sup> report a case of histoplasmosis in which the chief lesion was an ulcerative enteritis. A similar involvement was present in 8 of 25 carefully studied cases. Examination of stools in such cases may reveal the histoplasmas. The almost constant involvement of the mesenteric lymph nodes points, according to Henderson, to the gastrointestinal tract as the port of entry.

The parasites occur in various phagocytic cells as well as in the fixed reticuloendothelial cells of the liver and spleen. The site of predilection for the invasion by the yeastlike organism is the reticuloendothelial system. The bodies are found in the phagocytic cells in numbers of one to fifty. They may be found in thin smears of peripheral blood, by spleen, liver, lymph node or sternal puncture, and in biopsies from lymph nodes or cutaneous lesions.

Recently Humphrey<sup>6</sup> noted 5 cases of the disease in a limited area in Michigan. Within the year 1940, 9 cases occurred. Humphrey believes that the increase is actual and results from infection probably brought about by increased facilities for transport. The site of entry is uncertain, the skin has been suggested with possible bites or infestations by parasites as the mode of entry but the port most commonly accepted is the

lungs. They appear to be the site of the oldest and most dense involvement. Henderson believes that the gastrointestinal route is perhaps the site of entry, especially in cases showing ulcerative lesions in the alimentary tract with mesenteric lymphadenopathy. The disease so far has been invariably fatal. Meleney believes that antimony preparations, not only the monogamic salts but the trivalent preparations such as fuadin, and the pentavalent preparations such as neostam, should receive particular attention in therapy.

## Current Comment

### REORGANIZING BRITISH MEDICAL SERVICE

A discussion of "A National Medical Service and Conditions of Medical Practice After the War" by Sir Henry Brackenbury, M.D., in the *British Medical Journal* for January 24, probably the last article written before his death, forecasts some of the problems which will affect the practice of medicine in Great Britain after the war. An anticipated reduction of 3,540,000 in the population of England and Wales by 1965 means that some 4,500 fewer practitioners will be required by that date, assuming the present average "doctor power" to be satisfactory. A rise in the income limit for admission to national health insurance and the expected inclusion of dependents will bring some 80 to 85 per cent of the population under that system. The impoverishment by war taxation of the uninsured will still further restrict the scope of private practice. As a result of contemplated extension of the school medical service, "unless efforts, contrary to past experience, are successful, practitioners will lose contact with most children and young persons before their entry to the national health insurance system or even up to 18 years of age." In view of these facts "it is clear that opportunities for purely private practice—whether general, consultant or specialist—of a remunerative character are likely to be greatly curtailed and that all classes of practitioners must be prepared to accept some measure of contractual practice under the supervision of the Ministry of Health." It was Sir Henry's belief that the basis of any scheme of medical service would be the general practitioner and that it would be organized "on the general lines of the national health insurance scheme." This would not preclude, he thought, the widest reconsideration of the terms and conditions of service for practitioners or of the removal of many of the functions of the "approved societies" or even their abolition, or of changing the methods of financing the scheme. It does, however, "imply the continuance of at least four principles so far as the medical profession is concerned. These are (1) the right of any and every registered practitioner to take part in the service if he so choose, (2) the right of free choice between patient and doctor within reasonable territorial and numerical limits, (3) the position of the practitioner as an independent unit in the service not subject in his purely professional judgments to any lay authority or to any medical superior officer, (4) remuneration approxi-

mately proportional to the responsibility undertaken." Probably a number of services would be added to the present general practitioner service. "Such would be (1) a maternity and infant welfare service for expectant mothers, women during and shortly after childbirth, and infants up to 2 years of age, (2) a school medical service for children and young persons attending school full time, (3) a special diseases service, as for tuberculosis, venereal diseases, cancer and, possibly, rheumatism, (4) an industrial medical service dealing with the conditions of those engaged in certain industries, (5) a consultant medical service, (6) a hospital medical service comprising institutions for resident medical treatment of all kinds." On the administrative side Sir Henry saw the abolition or reduction in influence not only of the approved societies but also of a wide variety of minor local and often overlapping organizations, with which would come a unification and centralization of authority in regional and sometimes national bodies. This, he said, would require higher qualifications for medical officers of health and this, in turn, might involve important changes in medical education. Thus, as American "slanguage" would say, "comes the revolution." These are parlous times. The patterns are being designed for the world of the future. The message of Sir Henry Brackenbury sounds the "alert" for American medicine.

### TUBERCULOSIS AMONG MEDICAL STUDENTS

Pulmonary tuberculosis is one of the great occupational hazards of medical students and nurses. Indeed, in the 1938 report of the Association of Medical Students Committee on Student Health an average tuberculosis rate of 7 per cent in all medical schools was estimated, although less alarming figures are obtained from several of the medical schools at which control studies have been made. A 0.2 per cent incidence has been reported from Cornell, a 0.4 per cent case rate at Columbia and similarly low figures at Stanford, Wisconsin and Yale and other schools with well established health programs. The success of these control programs, Weinerman and Coe<sup>1</sup> believe, points the way toward which all student health services must strive. The first emphasis of the controlled program must be on prevention, with the effort principally directed toward the environment and contact with patients or laboratory materials. The living and eating conditions of the students should be supervised and maintained at standards compatible with good health in order to elevate the levels of student resistance. Proper opportunities for recreation and exercise should be provided. In addition, due precautions should be taken to eliminate any potential reservoir of infection in restaurant, boarding house and hospital personnel and in necropsy and laboratory rooms to prevent the escape of tubercle bacilli. Tuberculin testing should be performed on admission to medical school and at intervals thereafter. It must be recognized likewise that periodic

<sup>1</sup> Weinerman, E. R., and Coe, F. O. The Control of Tuberculosis Among Medical Students with Additional Reference to Student Nurses, *Journal of the American Medical Association* 62: 115 (April) 1942.

examination is the only sure method of recognition of the disease. The entire problem has become especially pressing in the light of the speed up program of medical education which may be expected to influence students to take short cuts in maintaining their resistance. In this battle to maintain health the Tuberculosis Committee American Student Health Association,<sup>2</sup> is assuming a valuable role.

### IMPROVEMENT OF HEALTH IN TWENTY-FIVE YEARS

The health of the American people is essential in the war effort. Fortunately the country has never been better fortified in this regard than it is today. A succession of noteworthy discoveries in medical science and developments in public health have prepared us better for the hardships and vicissitudes of modern warfare than we were twenty-five years ago. The experience among industrial policyholders of the Metropolitan Life Insurance Company<sup>1</sup> proves that the adjusted death rate has been reduced slightly more than 50 per cent in the course of the last quarter century. This reduction has appeared in practically every important cause of death. Indeed the diseases of childhood and infancy have been virtually eliminated as a cause of death within this period thus resulting not only in a substantial saving of life at early ages but also the sparing of many disabling sequels of these diseases to young people living today. The death rate from tuberculosis among industrial policyholders has been reduced to about one-fifth that of 1917, the mortality from syphilis is less than half of what it was in 1917. Similar trends have been manifest for pneumonia, maternal mortality and appendicitis. For motor vehicle accidents, however, the rate has more than doubled since 1917—the one notable exception. The experience of this large group of industrial policyholders may be considered generally applicable to the nation as a whole.

### STUDENT SECTION

With its appearance in this issue the Student Section of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is being temporarily discontinued. The tremendous demands placed on the time of the medical student because of the accelerated program and the great requirement for space in the columns of THE JOURNAL necessary because of the war effort seem to make it inadvisable to continue to carry this section at least until after the war shall have ended. The Board of Trustees at a recent session gave careful consideration to the problem. It was then decided to omit the Student Section as here indicated. Nevertheless, it is hoped to publish in the news columns of THE JOURNAL all items of importance relating to medical education, particularly as affected by the war. Incidentally, more than four thousand medical students regularly subscribe to THE JOURNAL.

### GASOLINE RATIONING AND MOTOR TRAVEL TO ATLANTIC CITY CONVENTION

Physicians who plan to travel by automobile to the annual session at Atlantic City should keep in mind that a gasoline rationing program became effective on May 15 in states along the eastern seaboard. The ration area includes the states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia, West Virginia, North Carolina, South Carolina, Georgia, that part of Florida east of Apalachicola, the District of Columbia, and the city of Bristol, Tenn. Subject to certain exemptions not pertinent to physicians who will attend the convention, no person in the rationed area will be able to buy gasoline without a ration card. Three basic classes of cards are issued. The class A card will entitle the holder to purchase such minimum supplies of gasoline as may be publicly announced by the Office of Price Administration. Such cards are issued generally where the motor vehicle is used solely for pleasure. Persons customarily using their cars in driving to and from and in the course of their gainful occupation to an extent greater than would be permitted by the basic allotment given on A cards will be issued B-1, B-2 or B-3 cards, depending on the amount of gasoline for which they show a need. An X card, permitting the acquisition of unlimited quantities of gasoline, is issued to physicians and nurses and certain others included in this preferred category on the basis of a certification by the applicant that the motor vehicle for which the gasoline is desired is used entirely or almost entirely in connection with the professional duties of the applicant. Stated in the language of the Application for Gasoline Ration Card X (form OPA R-506) the physician applicant must certify that the gasoline will be used in a motor vehicle "for rendering medical services." Physicians who practice in the rationed area will no doubt have made application for and received their X ration card by now. The Office of Price Administration advises that these cards will be usable to procure gasoline in any state in the rationed area and may be used in connection with attendance at the Atlantic City session. Physicians coming into the rationed area will find it necessary, in order to procure gasoline, to obtain a ration card from a local rationing board in that area. Such boards, it is understood, will be conveniently located in all communities. In making plans to attend the convention by automobile physicians should keep these conditions in mind. Ration cards cannot be obtained in advance by mail, application must be made personally by the physician. While advice received from Washington would indicate that little delay may be anticipated in obtaining the cards, local conditions and reactions may interfere with an expeditious handling of the application. In view of all the circumstances and taking into consideration the difficulties incident to the replacement of automobile tires, physicians from a distance should give serious consideration to using means of transportation other than the automobile to attend the convention.

# MEDICINE AND THE WAR

*In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession*

## OCCUPATIONAL DEFERMENTS OF DOCTORS, DENTISTS AND VETERINARIANS

The following memorandum (I-420) was sent to all state directors by Lewis B Hershey, director of the Selective Service System, Washington, D C This amendment involves a change from Corps Area Committee of Procurement and Assignment Service to separate state chairmen for medical doctors, dentists and doctors of veterinary medicine and also a change with respect to the consideration of dependency in classifying such registrants

### NATIONAL HEADQUARTERS

### SELECTIVE SERVICE SYSTEM

21ST STREET AND C STREET N W

WASHINGTON, D C

January 28, 1942

Amended 4/28/42

MEMORANDUM TO ALL STATE DIRECTORS (I 363)  
LOCAL BOARD RELEASE (89)

SUBJECT Occupational Deferments of Medical Doctors, Dentists and Doctors of Veterinary Medicine (III)

1 Information previously distributed by this headquarters clearly indicates an overall shortage of medical doctors, dentists and doctors of veterinary medicine in the nation Since war was declared, the shortage of these professional men has become acute It is now manifest that every qualified doctor, dentist and veterinarian must serve where he can render the greatest professional service to the nation

2 In order to accomplish this purpose, the President, by executive order, has formed the Procurement and Assignment Service This service was formed primarily for the purpose of gathering and making available information with respect to

the supply of qualified practitioners in the fields of medicine, dentistry and veterinary medicine, with a view of securing the most effective allocation of medical manpower as indicated by the requirements of the armed forces, civilian needs and industrial medicine

3 To work with the headquarters of the Procurement and Assignment Service there has been appointed for each state and the District of Columbia a state chairman for medical doctors, a state chairman for dentists and a state chairman for doctors of veterinary medicine These state chairmen will secure information concerning their respective professions and will give advice regarding the allocation of medical manpower

4 When considering the classification of any registrant who is a qualified medical doctor, dentist or doctor of veterinary medicine, the director of Selective Service desires that local boards, through the state director, shall consult with the respective state chairman of the Procurement and Assignment Service

5 In considering the classification of a registrant who is a qualified medical doctor, dentist or doctor of veterinary medicine, the local board may, if it finds such registrant should not be deferred for reasons other than dependency, take into consideration the pay and allowances which such registrant would receive in the event he is commissioned in the armed forces In practically all instances the pay and allowances of such registrant, if he was commissioned as an officer, would be sufficient to eliminate the question of dependency

6 For the convenience of the state director and the local boards, the names and addresses of the respective state chairmen of the Procurement and Assignment Service are listed here with

## WAIVER OF PHYSICAL DEFECTS FOR LIMITED SERVICE OFFICERS

The Surgeon General of the U S Army announced April 3 the following policies of his office concerning recommendations for waiver for limited service officers. These policies were announced in order that the provisions of AG-210 31 (12-19-41) RP-A Jan 7, 1942, may be carried out in a uniform manner.

### 1 a Considered acceptable for limited service

(1) Overweight to 25 per cent above average weight for age and height, and even greater degrees of overweight, provided the individual is not decidedly obese and provided that because of his special training in civil life he is peculiarly fitted to fill a particular technical assignment in the Army, and underweight to 15 per cent below ideal weight, provided chest x-ray examination is negative for pulmonary pathologic conditions and other chronic disease is carefully excluded.

(2) Any degree of uncorrected vision, provided it is corrected with glasses in possession of the examinee to 20/20 in one eye and to 20/40 in the other and provided that no organic disease of either eye exists.

(3) Blindness or corrected vision below 20/40 in one eye with vision 20/200 corrected with glasses in possession of the examinee to 20/20 in the other, provided there is no organic disease in the better eye and no history of cataract or other disease in the more defective eye which might be expected to involve the better one, and provided that in case of ophthalmosclerosis the individual is fitted with a satisfactory prosthesis.

(4) Complete color blindness.

(5) Hearing 5/20 in each ear for low conversational voice, or complete deafness in one ear with hearing 10/20 or better in the other, provided the defect is not due to active inflammatory disease and is stationary in character.

(6) Chronic otitis media, inactive, with perforation of membrana tympani, provided there is a trustworthy history of freedom from activity for the preceding five years.

(7) Old fracture of the spine or pelvic bones which has healed without definite deformity, provided there is a trustworthy history of freedom from symptoms during the preceding two years.

(8) Loss of one hand, one forearm, or one lower extremity below the junction of the middle and lower thirds of the thigh, provided the lost member is replaced with a satisfactory prosthesis.

(9) Pes planus, pes cavus or talipes equinus, provided the condition is not more than mildly symptomatic, does not interfere with normal locomotion and has not interfered with the individual's vocation in civil life.

(10) History of osteomyelitis following fracture, provided x-ray examination indicates complete healing and the condition has been asymptomatic for the preceding five years.

(11) Joints fixed or limited in motion, provided the condition is the result of injury and is nonsymptomatic.

(12) History of excision of torn or detached semilunar cartilage of knee joint, provided there is normal stability of the joint and a period of one year with complete freedom from symptoms has elapsed since the operation.

(13) Residuals of anterior poliomyelitis, without pronounced deformity or loss of function, originating two years or more prior to examination.

(14) Varicose veins, moderate, without edema or discoloration of skin.

(15) History of gastric or duodenal ulcer, provided there is a trustworthy history of freedom from activity during the preceding five years and provided that the gastrointestinal roentgenogram at the time of examination is negative.

(16) Incomplete inguinal hernia.

(17) Small asymptomatic congenital umbilical hernia.

(18) Absence of one kidney, provided its removal has been necessitated by other than tuberculosis or malignancy and the other kidney is normal.

### b Considered unacceptable for any service

(1) History of malignant disease within preceding five years.

(2) Active tuberculosis of any organ and inactive pulmonary tuberculosis except as described in paragraph 2a.

(3) Syphilis, except adequately treated syphilis as described in paragraph 2b.

(4) Old fracture of the skull with bony defect greater than 2 cm in longest diameter or with history of accompanying mental or neurologic complications.

(5) Instability of any of the major joints.

(6) History of metastatic osteomyelitis with prolonged or recurrent drainage, regardless of duration.

(7) Arthritis of the atrophic (rheumatoid) type.

(8) Any cardiovascular condition which disqualifies for general military service.

(9) History of gastroenterostomy, gastric resection, intestinal anastomosis or operation for intestinal obstruction.

(10) History of prostatectomy or transurethral resection of prostate or of prostatic hypertrophy of any degree.

(11) Chronic endocrine disease except mild hypothyroidism or mild Froehlich's syndrome.

(12) Diabetes mellitus of any degree or renal glycosuria.

(13) History of any psychosis.

(14) History of severe psychoneurosis at any time, or psychoneurosis of any degree if it has been recurrent or has shown symptoms within the preceding five years.

2 The following may be recommended for general military service with waiver.

a Individuals with minimal inactive lesions of primary or reinfection type pulmonary tuberculosis. These lesions may consist of

(1) Calcified residues of lesions of the intrathoracic lymph nodes, provided none of these exceed an arbitrary limit of 1 cm in diameter and the total number does not exceed five.

(2) Calcified lesions of the pulmonary parenchyma, provided the total number does not exceed ten, one of which may equal but not exceed 1 cm in diameter, but none of the remainder may exceed 0.5 cm in diameter.

(Note: The lesions described in (1) and (2) should appear sharply circumscribed, homogeneous and dense. Measurements refer to standard 14 by 17 inch direct projection roentgenograms.)

(3) Small fibrotic parenchymal lesions represented in a roentgenogram as sharply demarcated strandlike or well circumscribed small nodular shadows not exceeding a total area of 5 sq cm provided acceptance is deferred until subsequent examination.

demonstrates that the lesions are stationary and are not likely to be reactivated. The minimum period of time to determine this is six months. It must be recognized that either progression or regression of the lesions indicates activity.

b Individuals with confirmed position serologic tests for syphilis with no clinical evidence of the disease, with convincing histories of a trustworthy diagnosis of syphilis or with reliable histories of treatment for the disease on serologic or clinical grounds, provided

(1) That a negative spinal fluid since infection and treatment has been reported from a trustworthy source,

(2) That in infections estimated to be of less than four years' duration, at least thirty to forty arsenical and forty to sixty insoluble bismuth injections or their equivalent, with a minimum total of seventy-five injections, have been given, with approximate continuity (no rest periods or lapses) during the first thirty weeks of treatment, and

(3) That except as further qualified, in infections estimated to be over four years' duration at least twenty arsenical injections and forty to sixty insoluble bismuth injections or their equivalent, with a minimum total of sixty injections, have been given in alternating courses, rest periods between consecutive courses not exceeding eight weeks being allowable.

In infections of unknown duration it shall be presumed for classification purposes that those of individuals under 26 years of age are of less than four years' duration and over 26 years of more than four years' duration.

(Note: For the determination of treatment the signed statement of acceptable treatment sources administering it with total number of doses of each drug and approximate calendar dates of administration and available laboratory and clinical data shall be required as evidence.)

c Overweight to 20 per cent above average weight for age and height, and underweight to 12.5 per cent below ideal weight, provided chest x-ray examination is negative for pulmonary pathologic conditions and other chronic disease is carefully excluded.

d Insufficient incisor or masticating teeth, provided the mouth is free from extensive infectious processes and the examinee is wearing satisfactory dentures.

e Pilonidal cyst or sinus, provided there is no palpable tumor mass, no evidence of purulent or serous discharge and no history of previous discharge or inflammation.

f History of healed fracture with bone plates, screws or wires used for fixation of fragments still in situ, provided x-ray examination shows no evidence of osteomyelitis and no rarefaction

of bone contiguous to the fixative materials, that such fixative materials are not so located that they will be subjected to pressure from military clothing or equipment, and that one year has elapsed since their application.

g History of operation or of injection treatment for inguinal or small ventral hernia, provided examination three months or more following operation, or following the last injection, shows a satisfactory result.

h History of unilateral renal calculus, provided the condition has been asymptomatic for the preceding three years, urine examination is negative and roentgenologic examination (flat plate) of both kidneys is negative.

i Absence of the spleen, provided its removal has been necessitated by a crushing injury.

j History of cholecystectomy, provided the condition has been asymptomatic for the preceding two years.

3 The action of the reviewing medical authority should indicate on the Report of Physical Examination W D, A G O Form No 63, that cognizance has been taken of any defects which do not meet the standards set forth in AR 40-105, but for which waiver is recommended by a notation as follows:

'Recommend acceptance for general military service with waiver of (here record the defect or defects), or

Recommend acceptance for limited service only with waiver of (here record the defect or defects).'

4 It should be understood that this communication sets forth the policy of this office with regard to recommendations for waiver in the case of applicants for appointment and officers of the Reserve components under consideration for extended active duty. It is not intended that officers already in active service shall be recommended for appearance before retiring boards because of defects which would be considered disqualifying according to the policies set forth. The recommendations of disposition boards of general hospitals will be based on the principle that officers should be retained on active duty as long as they are capable of rendering efficient service unless they have conditions not incident to the service which are likely to progress to incapacity and eventually result in retirement in line of duty. The findings of disposition boards should clearly indicate that the officer under consideration is physically fit for limited service only when such is the case.

By order of the Surgeon General

JOHN A ROGERS,  
Colonel Medical Corps,  
Executive Officer

## TWENTY-SEVEN MEDICAL RECRUITING BOARDS

According to the *Army and Navy Journal* the War Department has released the names of members of twenty-seven recruiting boards in states east of the Mississippi River who will commission medical officers. The recruiting boards for states west of the Mississippi will be announced at a later date following completion of arrangements by Lieut Col James R. Hudnall M C, in the office of the Surgeon General and Lieut Col Sam F. Seeley, M C, of the Procurement and Assignment Service.

Members of the state boards are:

Alabama—Lieut Col A R Nichol Infantry and Major G C Woodruff M C.  
Connecticut—Major E E Williams M C and Capt H F Moore Infantry.  
Delaware and Southern New Jersey—Major A B van Raalte Adjutant General's Department and Capt R H Lowe M C.  
Maryland and District of Columbia—1st Lieut E B Sirota M C and 1st Lieut Samuel T Fisher Infantry.  
Florida—Major W E Murphree M C and Major J J Laird Infantry.  
Georgia—Lieut Col B G Owens M C and Capt Thomas H Folk Infantry.  
Illinois—Lieut Col R L Olmstead M C and Major John F Cardner Infantry.  
Indiana—Capt J H Miller Infantry and Capt Clarence E Northrup M C.  
Kentucky—Capt H J Brinker M C and Capt H C Lockhart Adjutant General's Department.

Louisiana—Major George R Benton M C and Capt J H Fox Infantry.  
Maine—Capt W P Weber M C and 1st Lieut R C Maxant Infantry.  
Massachusetts—Lieut Col Alexander Marble M C and Capt T J Quinn Infantry.  
Michigan—Lieut Col Paul T Priestly Infantry and Major John J Slevin M C.  
Mississippi—Major C D Mitchell M C and Capt William C Edgeworth Infantry.  
New Hampshire—Capt E L Wiemers M C and 1st Lieut R G Vedeler Cavalry.  
New York (northwestern)—Col Arthur T Boettcher Infantry and Major Edward K Reid M C.  
New York (southern) and New Jersey (northern and central)—Major William D Thornton Infantry and Capt J J McMahon M C.  
North Carolina—Major McKinnon Carmichael Infantry and Major Roy C Tatum M C.  
Ohio—Major Lewis W Cellio M C and 1st Lieut H S Wilson Adjutant General's Department.  
Pennsylvania—Major Gerald M Fluegel M C and Major E A Curran.  
Rhode Island—Lieut Col G W Well M C and 2d Lieut Paul M Fontaine.  
South Carolina—Lieut Col W C Goley M C and Major William Phillips Infantry.  
Tennessee—Lieut Col R C Rieburg Field Artillery and Capt R B Christman M C.  
Vermont—Major F E Lewis M C and 1st Lieut Henry E Dohler Cavalry.  
Virginia—Capt R M Jacobson M C and Capt John B Clark Infantry.  
West Virginia—Capt Richard D Farnack Cavalry.  
Wisconsin—Lieut Col Amorv A Miller Infantry and Capt Norman L Sheebe M C.

### DAYTON SPECIALIST UNIT ORDERED OVERSEAS

Medical Specialist Unit No 57, U S Naval Reserve, composed of physicians from Dayton, Ohio, which was one of the first units of this kind to be called to active duty and stationed at a naval hospital in this country, has been ordered overseas. The officers comprising the unit are Comdr Walter M Simpson, internist, and Lieut Comdrs Marion W Coleman, urologist, Harry R Huston, surgeon, Jerome Hartman, orthopedist, Lawrence F Patterson, dental surgeon, James L Sagebiel, neuropsychiatrist and Lieuts Norman J Birkbeck, roentgenologist, Thomas P Sharkey, alternate internist, and Paul L Yordy, anesthetist. According to the *Ohio State Medical Journal* this unit was organized in 1935 by Commander Simpson at the request of the Surgeon General of the Navy.

### TWO NEW REAR ADMIRALS

President Roosevelt has approved the promotion to rear admiral of Capts Dallas G Sutton and Charles W O Bunker of the U S Navy Medical Corps. Captain Bunker, who is at present in command of the Navy Medical School, Washington, D C, graduated from Cornell University in 1905 and joined the Navy as assistant surgeon two years later. He served with the Navy in European waters during the first world war and later on the U S Hospital Ship *Relief* and at the naval hospitals in New York and Washington. Captain Sutton, who at present is in command of the Norfolk Naval Hospital, Portsmouth, Va, graduated from George Washington University School of Medicine in 1906 and was appointed assistant surgeon in the Navy in 1907. He has served on the U S Hospital Ship *Relief*, the U S S *Mellville*, at the naval hospitals at Pensacola, Fla, and Great Lakes, Ill, at the Naval Academy, Annapolis, Md, and was formerly in command of the Navy Medical School.

### STATE HEALTH DEPARTMENT FOLLOWS UP REJECTEES

In a program to rehabilitate selective service men deferred on account of tuberculosis, the Illinois state health director, Dr Roland R Cross, announces that so far out of 594 men deferred for tuberculosis in Illinois since November 1940 the state health department has found only 21 who previous to their deferment had been reported to the state health department as having had tuberculosis. The health department has arranged to reexamine the entire remaining group through Medical Advisory Board No 39 in order that the active tuberculous cases may be cared for through the usual channels and the men with inactive lesions referred to their own physicians for medical supervision. Dr Cross said that a man is not acceptable to the army for active military duty if he has five or more calcified spots on his lungs, however, such men can safely carry on ordinary civilian activities without undue fear of relapse.

### GRADUATION AT CARLISLE BARRACKS

Two hundred and sixty-six officers of the medical department of the army graduated from the Medical Field Service School at Carlisle Barracks, Pa, May 2, after completing two months' field training. The ceremonies were held in the post theater at Carlisle Barracks, which is one of the oldest army posts in this country. The address was made by Brig Gen Addison B Davis, Assistant Surgeon General of the Army. The class represented forty states, the District of Columbia and Haiti and comprised one hundred and seventy-one officers of the medical corps, sixty-two of the dental corps, twelve of the veterinary corps and twenty-four of the medical administrative corps. The class also comprised two hundred and fifteen reserve officers, thirty-nine National Guard officers, and twelve regular army officers, and the various ranks were represented from second lieutenants to lieutenant colonels. This was the twelfth class to graduate at Carlisle Barracks. Another class of officers began this course of instruction on May 9.

### COMMISSIONS FOR DENTAL AND VETERINARY STUDENTS

Physically qualified male citizens of the United States above the age of 18 years who are bona fide accepted matriculants at approved dental or veterinary schools in the United States may now be appointed as second lieutenants, Army of the United States, Medical Administrative Corps. Officers so appointed will not be ordered to active duty until eligible for appointment as first lieutenant in the Dental or Veterinary Corps of the Army. Applications and accompanying papers must be forwarded by the dean of the dental or veterinary school to the commanding general of the corps area in which the school is located, together with a certified statement that the applicant is a bona fide accepted matriculant in dentistry or veterinary medicine at the institution.

Dental and veterinary students so appointed will be discharged for the convenience of the government, under the following circumstances:

- (a) Discontinuance of dental or veterinary education
- (b) Matriculation at an unapproved school of dentistry or veterinary medicine
- (c) Failure to complete successfully the four year course of dental or veterinary instruction
- (d) Failure to secure appointment in the dental or veterinary corps of the Army within three months after completion of the prescribed four year course of dental or veterinary instruction

### CHANGES IN ARMY CORPS AREAS

The following changes have been made by the War Department in the states composing the various U S Army corps areas. Louisiana has been taken from the fourth corps area and placed in the eighth corps area, Colorado has been taken from the eighth corps area and placed in the seventh, and Arizona has been taken from the eighth corps area and placed in the ninth corps area. The corps areas as now constituted comprise the following states:

|                      |                |               |
|----------------------|----------------|---------------|
| <i>First</i>         | South Carolina | Iowa          |
| Maine                | Alabama        | Kansas        |
| Vermont              | Georgia        | Missouri      |
| New Hampshire        | Mississippi    | Arkansas      |
| Rhode Island         | Florida        | Wyoming       |
| Massachusetts        | <i>Fifth</i>   | Colorado      |
| Connecticut          | Ohio           | <i>Eighth</i> |
| <i>Second</i>        | West Virginia  | New Mexico    |
| New York             | Indiana        | Oklahoma      |
| New Jersey           | Kentucky       | Texas         |
| Delaware             | <i>Sixth</i>   | Louisiana     |
| <i>Third</i>         | Wisconsin      | <i>Ninth</i>  |
| Pennsylvania         | Illinois       | Washington    |
| Virginia             | Michigan       | Montana       |
| District of Columbia | <i>Seventh</i> | Oregon        |
| Maryland             | North Dakota   | Nevada        |
| <i>Fourth</i>        | South Dakota   | Utah          |
| Tennessee            | Minnesota      | California    |
| North Carolina       | Nebraska       | Idaho         |
|                      |                | Arizona       |

### HAWAII MEDICAL JOURNAL

The January 1942 issue of the *Hawaii Medical Journal* is the first volume of this periodical published since the Japanese raid on Pearl Harbor. Most of the articles have to do with the medical experiences immediately following December 7 and with the methods of treatment of air raid injuries carried out at the results of treatment, there is also an illustrated chart of various warfare gases pointing out how to detect their presence, their physiologic effect, how to protect against them, treatment and other general instructions. The observations comprise not only those made at the U S Naval Hospital at Pearl Harbor and the Tripler General Hospital, Fort Shafter, but also some of the civilian hospitals in Honolulu.

### OHIO PHYSICIANS ON BATAAN PENINSULA

Among the physicians who were known to be on the Bataan Peninsula in the Philippine Islands with General Wainwright were Major C G Jackson of Kenton and Lieut David P. of Columbus, graduates of Ohio State University School of Medicine in 1931 and 1935, respectively.

#### Transportation to Atlantic City

Fellows desiring to attend the Atlantic City session are urged to purchase transportation immediately

## MEDICAL LEGISLATION

### MEDICAL BILLS IN CONGRESS

*Change in Status*—H R 4476 has passed the Senate, providing for sundry matters affecting the military establishment. As passed by the Senate, this bill retains an authorization for the employment of interns in army hospitals who are graduates of or have successfully completed at least four years' professional training in reputable schools of medicine or osteopathy, at not to exceed \$720 per annum. An amendment agreed to by the Senate continues in force the provisions of this bill during the present war and for six months after the termination of the war, or until such earlier time as the Congress by concurrent resolution or the President by proclamation may designate.

*Bills Introduced*—The President has submitted a supplemental estimate of appropriation for the Public Health Service, amounting to \$5,420,000 for the fiscal year 1943. Of the amount included in the estimate, \$5,000,000 will be used by the Public Health Service to undertake directly in defense areas measures to control mosquitoes in connection with the suppression of malaria and to control dog flies near Eglen and Tyndall airfields and a school of flexible gunnery in Florida. The remainder of the estimate, \$420,000 will be used to con-

tinue a program, for which an allotment from the President's emergency fund has been made, to provide sufficient reserves of blood plasma in two hundred hospitals to meet any wartime contingency caused by enemy action which may necessitate blood transfusions to civilians. H R 7042, introduced by Representative Celler, New York, contemplates amendment of the United States Employees' Compensation Act so as to provide compensation for air raid wardens and other civilian defense workers who suffer traumatic injury while engaged in an approved course of training or while performing civilian defense duties. H R 7029, introduced by Representative Sparkman, Alabama, proposes numerous amendments to the Soldiers' and Sailors' Civil Relief Act of 1940, to provide further relief for persons in military service. Among other proposed changes, the bill would extend the provisions of the act relating to leases to cover premises occupied for professional, business, agricultural or similar purposes in any case in which (a) such lease was executed by or on the behalf of a person who, after the execution of such lease, entered military service and (b) the premises so leased have been occupied for such purposes, or for a combination of such purposes, by such person or by him and his dependents.

### DISTRICT OF COLUMBIA

*Change in Status*—H R 6362 has been reported to the House of Representatives, proposing to impose an annual registration requirement on persons licensed to practice the healing art in the District of Columbia. The annual registration fee will be \$2. The bill proposes further to amend the healing arts practice act so as to provide that all expenses incident to criminal prosecutions and to supervision and investigation with a view to criminal prosecution shall be paid from the fees collected under the act. Heretofore such expenses have been paid from appropriations in the same manner as the expenses of other criminal prosecutions and supervisory work and investigations incident thereto are paid.

## WOMAN'S AUXILIARY

### District of Columbia

The Woman's Auxiliary to the Medical Society of the District of Columbia met in the Medical Society Building on January 14 with Mrs. Caryl Burbank the president, presiding. The guests included Mrs. William L. Walters, president of the Woman's Auxiliary to the Dental Society of the District of Columbia. Miss Mabel T. Boardman of the American Red Cross. Major Julia O. Flikke of the Army Nurses Corps, Miss Sue S. Dauser and Mesdames Ross T. McIntire, Robert E. Hoyt, James Magee, Shelly U. Marietta, S. S. Adams, Hugh S. Cumming, Merritt W. Ireland, Thomas Parran, Walter Reed, Charles Edward Riggs, P. S. Rossiter, William M. Sprigg, Edward R. Stitt, D. P. Hickling and Cline N. Chipman. It is planned to present the glee club of Duke University in a concert in March. The proceeds will be placed in the educational fund. A first aid course under the sponsorship of the American Red Cross is being held in the medical society's library. Fifty-four auxiliary members are enrolled.

### Michigan

The Bay County auxiliary held an open meeting on January 7. Dr. John Sheldon of the University of Michigan Hospital, Ann Arbor, gave an illustrated lecture on "The Modern Concepts of Allergic Diseases." Over two hundred persons attended.

The Kent County auxiliary met on January 14. The auxiliary decided to organize a class to take the Red Cross course in home nursing and also voted to invest part of its benevolence fund in seven defense bonds of the \$100 denomination. L. E. Murphy of the Federal Bureau of Investigation spoke on the F. B. I. in Relation to Defense.

### Minnesota

The Ramsey County Auxiliary Red Cross unit was organized recently with Mrs. Harvey Beek and Mrs. John Madden in charge. It meets at Hope Church, St. Paul and makes surgical dressings and bandages and does sewing and knitting.

### Texas

The Bexar County auxiliary voted to dispense with all social functions for the year and to give the money used ordinarily for decorations and for tips to the Red Cross fund.

The auxiliary gave a party in the recreation room of the Bexar County Medical Society on January 8 for fifty soldiers and twenty-five student nurses.

Two first aid classes are conducted four times each week for members of the auxiliary. Many members are making surgical dressings.

The Nine Counties (Medina - Uvalde - Maverick - Valverde - Edwards - Real - Kinney - Terrell - Zavala) auxiliary was reorganized, Dec. 12, 1941, at Uvalde, with fourteen members and guests present. Mrs. E. W. Covle, fourth vice president of the state auxiliary, Mrs. Max E. Johnson and Mrs. M. J. Cooper of San Antonio assisted in the reorganization. The following officers were elected: Mrs. E. C. Bourdon, Uvalde, president; Mrs. T. M. Johnson, Del Rio, vice president; Mrs. George E. Merritt, Uvalde, secretary-treasurer and Mrs. A. P. Utterback, Bracketville, reported. Because of the great distances between homes of members of the auxiliary the organization will limit activities to war and Red Cross work.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 299

### ARIZONA

**State Medical Meeting at Prescott, May 25-30**—The Arizona State Medical Association will hold its annual meeting at the Hassayampa Hotel in Prescott, May 25-30, under the presidency of Dr. W. Paul Holbrook, Tucson. The host will be the Yavapai County Medical Society. The speakers at the opening session will include the mayor of Prescott and the governor. The preliminary program lists the following speakers, among others:

Dr. Walter Bauer, Boston, Arthritis  
Dr. Noble Wiley Jones, Portland, Ore., Arteriosclerosis  
Dr. Verne C. Hunt, Los Angeles, Lesions of the Stomach  
Dr. Howard P. House, Los Angeles, Diseases Related to the Middle Ear  
Dr. Frank Himmman, San Francisco, Urologic Conditions in Women  
Dr. William A. Boyce, Los Angeles, Anesthesia and Procedure of Safety in Eye Operations  
Dr. Alfred J. Ridges, Salt Lake City, Ethmoiditis, Common Colds  
Dr. Isaac H. Jones, Los Angeles, Ear Conditions in General Medicine

Most of the program has been divided into symposiums and panel discussions, one of which will be devoted to silicosis and other industrial dust diseases. Drs. Leroy U. Gardner, Saranac Lake, N. Y., Anthony J. Lanza, Washington, D. C., and Donald E. Cummings, B. S., Denver, will be among the speakers.

### CONNECTICUT

**Industrial Health Forum**—The industrial health and safety committee of the Manufacturers Association of Connecticut, Inc., and the state medical society sponsored their first industrial health forum at the New Haven Lawn Club, New Haven, May 7. One session was devoted to a discussion by personnel managers on employee health problems. Speakers on the program included:

William M. Grafer, D.Sc., U. S. Public Health Service, Bethesda, Md., **Sickness Among Industrial Workers—Bottleneck in the Offense Program**  
T. O. Armstrong, industrial relations manager, Westinghouse Electric & Manufacturing Company, Springfield, Mass., **Experiences with an Industrial Health Program**  
Walter S. Paine, manager, engineering and inspection department, Aetna Life Insurance Company and the Aetna Casualty and Surety Company, Hartford, **Benefits from an Adequate Health Service**  
George R. Cowgill, Ph.D., associate professor of physiological chemistry, Yale University School of Medicine, New Haven, **Nutrition—Its Value to the War Program**  
Dr. George K. Pratt, medical director, Connecticut Society for Mental Hygiene, New Haven, **Solving Personal Problems**  
Dr. Crit Pharris, industrial hygiene physician, state department of health, Hartford, **Meeting the Health Needs of Individual Plants—Minimum Facilities**

Dr. Victor G. Heiser, New York, consultant, committee on healthful working conditions, National Association of Manufacturers, addressed the dinner session on "Industrial Health and the War Problem."

### DISTRICT OF COLUMBIA

**Doctors Hospital Accepts Group Patients Until End of Contract**—Doctors Hospital, Washington, has reached an agreement with Group Hospitalization, Inc., to admit subscribers until March 31, 1943, when the hospital will withdraw as a full participating institution in the hospitalization plan, according to the *Washington Star*, May 6. The decision was announced after a conference between officials of the two groups. Under the agreement the hospital will accept hospitalization subscribers whether the contract is existing, a renewal or a new one until the expiration of the contract on March 31. The arrangement settles a dispute made public on April 24, when the hospital announced it would not renew its contract as of next March 31 and also refused to care for any new persons signing up in the interim or any whose contracts have expired and been renewed (THE JOURNAL, May 9, p. 195).

### FLORIDA

**Dr. Munch Convicted on Fraudulent Mail Charge**—Dr. George A. Munch, at one time secretary of the old Florida Eclectic Examining Board, was sentenced on April 9 to serve five years in the penitentiary by Federal Judge Akerman.

Newspapers reported that Dr. Munch and Robert F. McFall, Williston attorney, were convicted on charges of using the mails to defraud the Florida medical examining board of fees for licensing physicians. McFall was sentenced to serve three years. Both men, who had been at liberty under bail, were taken into custody. Two naturopaths, who had pleaded *nolo contendere* to complicity in the scheme to defraud the medical board, were given two year suspended sentences and placed on probation for a two year period. They are Lyle P. Johnson, St. Petersburg, and Julio G. Lopez, Tampa. Johnson was named as a defendant in the indictment with Dr. Munch and McFall. The government charged that Johnson had bought an illegal certificate to practice medicine in Florida from Dr. Munch, through the assistance of McFall. Lopez and Munch were named as co-defendants in another indictment, which charged that Lopez had obtained an illegal medical certificate from Munch. In 1927 Munch stood trial with other defendants on a charge of using the mails to defraud in connection with the sale of medical diplomas and licenses. At that time he was sentenced to the federal prison at Atlanta for a term of five years and to pay a fine of \$1,000. Dr. Munch is now 80 years of age. His license to practice medicine in Florida has been revoked and reinstated on various occasions.

### GEORGIA

**New Professor of Internal Medicine**—Dr. Eugene A. Stead Jr., instructor in medicine, Harvard Medical School, Boston, has been appointed to head the department of internal medicine at Emory University School of Medicine, Atlanta, newspapers reported on March 15. Dr. Stead graduated at Emory in 1932. He will devote his entire time to educational and research activities, it was stated.

**Municipal Health Center Building Dedicated**—The city of Savannah dedicated its new health center building, March 25. The three story building was constructed at a cost of \$100,000 as a joint city-WPA project and houses all of the official and nonofficial or voluntary health agencies incorporated into the organization known as the Savannah Health Center, directed by the city and county health department. The principal address at the dedication was delivered by Dr. Harry S. Mustard, director of the De Lamar Institute of Public Health, Columbia University, New York. Mayor Thomas Gamble in his address reviewed progress made in the field of health services in Savannah since the appointment of the first health officer in 1790. A commemorative plaque was unveiled as a part of the exercises.

### ILLINOIS

**New Health Center Building**—Ground was broken for the new Champaign-Urbana Health Center building on April 20. The unit, which will cost \$40,000, is the completion of a plan adopted when the district was organized in 1937, it was reported.

**Northwestern Alumni Luncheon**—The alumni of Northwestern University Medical School will hold a luncheon during the meeting of the Illinois State Medical Society in Springfield, May 20, at the Christ Church Parish House, 611 East Jackson Street. It will be necessary to register for the luncheon planned for 12:30.

**Personal**—Friends and colleagues of Dr. Marion K. Bowles, Joliet, gave a dinner in her honor recently in recognition of her many years of service to the community. The occasion also marked her retirement from the Joliet Township Health School Board, of which she has been a member for many years. She has served as president of the board six times. Dr. Bowles was formerly secretary-treasurer of the Western Grundy Counties Medical Society. She graduated at Northwestern University Woman's Medical School, Chicago, in 1911.

### CHICAGO

**Award Fellowship in Rheumatic Fever**—Dr. Roy L. Hayes of the Children's Memorial Hospital has been awarded the Morris Fishbein Jr. Fellowship for research on rheumatic fever. The fellowship is financed by a memorial fund established in honor of the late Morris Fishbein Jr., to carry out research in some phase of cardiovascular disease. The recipient of the fellowship is chosen by the trustees of the Chicago Association of Physicians. Dr. Hayes graduated at the University of Illinois College of Medicine in 1939. She will pursue her research at the Children's Memorial Hospital.

**Society News**—Among others, Dr. Owen H. Wangensteen, Minneapolis, addressed the Chicago Surgical Society, May 1, on "The Surgical Aspects of Peptic Ulcer"—The Chicago Orthopedic Society was addressed, April 10, in the Palmer House by Drs. John J. Fahey on "Circulation of the Head of the Femur" and Mauley A. Page, "Calcaneal Fractures Involving Articular Surfaces."

**Dr. Oliver-Gonzalez Wins Ricketts Prize**—Jose Oliver-Gonzalez Ph.D., Mr. and Mrs. Frank Logan fellow in bacteriology, department of bacteriology, Division of Biological Sciences, University of Chicago has been awarded the Howard Taylor Ricketts Prize for his research on "Dual Antibody Basis of Acquired Immunity in Trichinosis." Dr. Oliver-Gonzalez is a native of Puerto Rico. He received his B.A. degree at the University of Puerto Rico in 1938 and his M.A. and Ph.D. degrees at the University of Chicago in 1939 and 1941, respectively. The recipient of the Ricketts Prize is announced every year on May 3 the anniversary of Dr. Ricketts' death.

**Special Meeting of Institute of Medicine**—The Institute of Medicine of Chicago will hold a special meeting at the Palmer House, May 22, under the chairmanship of Dr. Andrew C. Ivy. The speakers will be Drs. Arnold Lazarow, winner of the 1941 Joseph A. Capps Prize for medical research, on "Particulate Glycogen: A Submicroscopic Component of the Guinea Pig Liver Cell, Its Significance in Glycogen Storage and the Regulation of Blood Sugar," Paul H. Holinger, "Kodachrome Visualization of the Physiology and Pathology of the Bronchi and Esophagus," and Jay M. Garner, Winnetka, Ill., and Jerrold Peerman, Nesselrode, Evanston, Ill., "Interesting Proctoscopic Observations in Color."

## INDIANA

**New Officers of Tri-State Association**—Dr. Howard H. Cummings, Ann Arbor, Mich., was elected president of the Northern Tri-State Medical Association at its annual meeting in Fort Wayne, April 7, succeeding Dr. Lyman T. Rawles, Fort Wayne. Dr. E. Benjamin Gillette, Toledo, Ohio, was reelected vice president. Dr. Floyd R. A. Carter, South Bend, was reelected secretary and Dr. Oscar P. Klatz, Findlay, Ohio, was chosen treasurer.

**Election of State Medical Board**—Dr. Hobart C. Rudick, Evansville, was elected president of the state board of medical examiners at the recent annual meeting, succeeding Dr. William C. Moore, Muncie, who was elected secretary. Dr. Jesse W. Bowers, Fort Wayne, who had been secretary, resigned from the board to become medical commander at Fort Benjamin Harrison, newspapers reported. Other officers of the board include Dr. Norris E. Harold, Indianapolis, vice president, and C. B. Blakeslee, D.O., Indianapolis, treasurer.

**Postgraduate Courses in Pediatrics**—A series of lectures on pediatrics, sponsored by the Perry County Medical Society in cooperation with the bureau of maternal and child health of the Indiana State Board of Health, opened in Cannelton on April 29 to continue each week until June 10. Dr. Walter R. Springston, Evansville, is the instructor. Two courses in obstetrics consisting of four lectures each, opened in Plymouth, April 20, and in Washington, April 28, under the auspices of the Marshall and Tri-County medical societies, respectively. Dr. Carl P. Huber, associate professor of obstetrics, Indiana University School of Medicine, Indianapolis, is giving the lectures.

## IOWA

**State Medical Election**—Dr. Lee R. Woodward, Mason City, was chosen president-elect of the Iowa State Medical Society at the recent annual session in Des Moines. Dr. Frank P. Winkler, Sibley, was installed as president. Other officers include Drs. Walter A. Sternberg, Mount Pleasant, and Walter D. Abbott, Des Moines, vice presidents, and Robert L. Parker, Des Moines, secretary-treasurer. Des Moines was selected as the place for the 1943 annual session.

**Annual Renewal Fees Due Before June 1**—All licenses to practice medicine and surgery in Iowa expire annually on June 30. To renew such a license a licensee must make a written application to the state department of health before June 1, enclosing the renewal fee of \$1. If a license expires by reason of the licensee's failure to renew it, it can be reinstated without reexamination only on the recommendation of the state department of health and the payment of the overdue fees.

## LOUISIANA

**Meeting of Urologists**—The fourth annual session of the Louisiana Urological Society was held at the St. Charles Hotel, New Orleans, April 30, under the presidency of Dr. Henry W. E. Walther, New Orleans. The speakers included:

Dr. Harry C. Knight, New Orleans, president, assistant surgeon, U.S. Public Health Service, Disease Control During the War Effort.  
Dr. Donald C. Maleholm, Clifton, Kan., major, U.S. Army, Report of Urologic Section of a General Hospital.  
Dr. James E. Gill, Washington, D.C., captain, U.S. Navy, Urology in the Navy.  
Dr. Alfred I. Folsom, Dallas, Texas, The Female Obstructing Prostate.  
Dr. Ansel M. Caine, New Orleans, Modern Trends in Anesthesia as Applied to Transurethral Procedures.  
Dr. Pierre Jorda, Kahle, New Orleans, Treatment of Prostatic Carcinoma and Metastases with Stilbestrol.  
Dr. Henry J. Lindner, New Orleans, The Effect of Castration in Metastatic Carcinoma of the Prostate.  
Dr. Robert F. Sharp, New Orleans, Aneurysm of the Renal Artery.  
Dr. John G. Menville, New Orleans, Gas Formation in Renal Abscess.

## MINNESOTA

**Society News**—Dr. William P. Sadler, Minneapolis, spoke on "Ectopic Pregnancy" before the Minnesota Academy of Medicine recently. The Minnesota Pathological Society was addressed April 7, in Minneapolis, by Dr. Alvin F. Coburn, New York, on "Role of Hemolytic Streptococcus in the Pathogenesis of Rheumatic Fever." Dr. Thomas Addis, San Francisco, gave a Mayo Foundation Lecture recently in Rochester on "The Treatment of Glomerulonephritis."

**Olmsted County Accredited in Tuberculosis Control**—Olmsted County has been awarded a certificate of accreditation by the Minnesota State Department of Health and the Minnesota State Medical Association in their joint program to accredit counties showing a tuberculosis mortality rate of less than 10 per hundred thousand of population and a record of less than 15 per cent reactors to the tuberculin test among the state's high school seniors. Olmsted County was the second in the state to achieve this honor. Lincoln County having been the first. Special ceremonies in Rochester will mark the presentation of the certificate on May 22 with Dr. Henry F. Helmholz, Rochester, president of the Olmsted County Public Health Association, presiding. Dr. Chester A. Stewart, professor of pediatrics and director of the department, Louisiana State University School of Medicine, New Orleans, will be the principal speaker.

## NEBRASKA

**New Public Health Personnel**—Dr. Vernon M. Winkle, Norfolk, has been named director of health unit number 1 covering Scottsbluff, Morrill and Banner counties and temporary director of health unit number 3 comprising Lincoln and Keith counties. Dr. Reuben Mutnick, New York, has been named director of the Dodge-Saunders defense area according to *Better Health*. Dr. William E. Holmes, Omaha, has been added to the state health department staff as medical health officer but at the time of this report had not been assigned to a unit.

## NEW JERSEY

**Personal**—Dr. Henry A. Davidson, editor of the *Journal of the Medical Society of New Jersey*, Trenton, has been ordered to active duty at the Army Medical Center in Washington, D.C.—Dr. Edward J. Ill, Newark, has been made a life emeritus member of the state publication committee of the Medical Society of New Jersey; he was first a member for one year beginning in July 1906 and has been continuously a member since July 1910.

## NEW YORK

**Personal**—Dr. Augustus J. Hambrook, Troy, has been appointed medical consultant in the Troy department of public welfare, a new position provided for in the 1942 city budget effective January 1.—Dr. Arthur E. Soper, Brentwood, has been named superintendent of the Kings Park State Hospital, Kings Park; he has been on the staff of the Pilgrim State Hospital, Brentwood, since 1932.

**Food Poisoning Traced**—A recent outbreak of food poisoning in an upstate city has been attributed to hollandaise sauce in which large numbers of hemolytic *Staphylococcus aureus* were found. The outbreak was traced to a restaurant. About five hours after ingestion of the meal the illnesses were characterized by profuse vomiting, purging and prostration. There were no deaths.

**Public Health Laboratories Meeting**—The twenty-sixth annual meeting of the New York State Association of Public Health Laboratories will be held in Schenectady, May 18, under the presidency of Dr. Francis F. Harrison, Cooperstown. Among the speakers will be Florence M. Varley and Dr. Frederick R. Weedon, Jamestown, on "The Use of Frozen Guinea Pig Serum in the Complement Fixation Test for Syphilis", Dr. Dorothy B. Chamberlin and Dr. William Kaufmann, Albany, "Meconium Ileus, a Clinicopathological Syndrome of Newborn Infants", Dr. Francis W. Porio, Ogdensburg, "Trichinosis," and Dr. Alan R. Moritz, Boston, "Integration of Medicolegal Pathology with Public Health Work."

#### New York City

**Dr. Geiling to Give Harvey Lecture**—Dr. Eugene M. K. Geiling, professor of pharmacology, University of Chicago School of Medicine, will deliver the eighth and last Harvey Society Lecture of the current series at the New York Academy of Medicine on May 21. His subject will be "The Comparative Anatomy and Pharmacology of the Pituitary Body."

**Exhibit Traces History of Hospital**—Special ceremonies on April 29 marked the opening of an exhibit at Mount Sinai Hospital which shows the history of the institution since 1852. The exhibit is a feature of the ninetyeth anniversary celebration of the hospital and consists of modern scientific displays, old time instruments and mementoes of medical pioneering and of service in United States wars. The main section of the exhibit will depict the development of the hospital against the background of contemporary, general and scientific history. The hospital has planned a year of celebration of its founding, including special lectures and other events.

**Jean Perrin Is Dead**—Jean Perrin, French physicist, winner of the Nobel Prize in 1926 and former president of the French Academy of Science, died April 17 in Mount Sinai Hospital, aged 71. Dr. Perrin, who was a member of the faculty of Paris University for many years, came to this country a few months ago. He had retired before the war but was in Paris when the war started. According to the New York Times through the cooperation of the faculty of Wilson College, Chambersburg, Pa., he was able to come here. The Nobel Prize in physics was awarded to Dr. Perrin for work on brownian movement kinetics, which dealt with so-called brownian particles. He was also honored for his work on the role of radiation in chemical reactions. He was educated at the Ecole Normale, Paris. He was founder of the department of physicochemistry at the Sorbonne and in 1938 was named president of the high committee for scientific research by the French government. Dr. Perrin was living with his son Francis Perrin, visiting professor of physics and mathematics at Columbia University.

**Violations of Marriage Examination Law**—On April 23 the New York Times reported that an investigation of irregularities in the marriage license bureau has disclosed indications that physicians are violating the law requiring a premarital examination by giving the couples only blood tests and not making physical examinations. William B. Herlands, commissioner of investigation, recommended that the department of health and the "organized medical profession" immediately undertake "appropriate educational and disciplinary steps necessary for the proper enforcement of the premedical examination law," the Times stated. Two employees of the marriage license bureau and one in the health department were ordered suspended as a result of the investigation. Herlands' report indicated instances of alleged "steering" of couples to certain physicians in the neighborhood of the bureau and the department. The report also said the inquiry has disclosed the possibility of "blood tests by proxy" because, it alleged, the physician named had accepted a blood specimen sent from another city as that of a woman and given her a medical certificate.

#### OHIO

**Emeritus Professors**—The title of professor emeritus was recently conferred on Dr. Mark A. Brown, professor of medicine, University of Cincinnati College of Medicine, Cincinnati, and Dr. Emerson A. North, professor of psychiatry. Dr. Brown has been professor at the school since 1900. Dr. North's retirement was noted in THE JOURNAL, January 17, page 240.

**Gifts for Research**—Funds totaling more than \$30,000 for research at the University of Cincinnati College of Medicine, Cincinnati, were accepted at the March meeting of the board. These gifts included \$9,500 from an anonymous donor for the Heart Station Fund in the department of internal medicine,

\$3,500 from an anonymous donor to the Porter Fund in Obstetrics, \$2,400 from the National Advisory Cancer Council to the department of surgery "to improve the present method of diagnosis and treatment of cancer," \$1,200 from the Lederle Laboratories, Inc., to the department of biologic chemistry and \$1,500 from an anonymous donor to the Craig Yeiser Fund in the department of preventive medicine.

#### OREGON

**Refresher Courses in Pediatrics and Obstetrics**—The Oregon State Medical Society and the state board of health are cooperating in a series of lectures on pediatrics and obstetrics. The program will be offered in the form of panel discussions by Oregon physicians. Dr. Henry Close Hesselbarger, Chicago, assistant professor of obstetrics and gynecology, University of Chicago School of Medicine, will be the guest lecturer. The series was given on May 11 at Ontario, May 12 at Baker, May 13 at Pendleton, May 14 at The Dalles, May 15 at Bend and will be given on May 18 at Lakeview, May 19 at Klamath Falls, May 20 at Medford, May 21 at Grants Pass, May 22 at Marshfield, May 25 at Astoria, May 26 at Portland, May 27 at Salem and May 28 at Eugene.

#### PENNSYLVANIA

**Industrial Hygiene Division**—Dr. Joseph Shilen, Pittsburgh, has been appointed head of the division of industrial hygiene of the state department of health, Harrisburg. He succeeds Dr. William B. Fulton, Harrisburg, who was appointed chief of the division of health in the U. S. Bureau of Mines. Dr. Shilen graduated at George Washington University School of Medicine, Washington, D. C., in 1916.

**Society News**—Dr. Michael M. Wolfe, Philadelphia, addressed the Luzerne County Medical Society, Wilkes-Barre, March 18, on "Indications for Plastic Surgery."—Dr. Adam C. Williamson, Pittsburgh, addressed the Mercer County Medical Society at Grove City, April 7, on "General Problems of Obstetrics in General Practice."—Dr. Herbert T. Kelly, Philadelphia, addressed the Lancaster City and County Medical Society in Lancaster, March 4, on "The Modern Science of Nutrition and Nutritional Deficiency."—The Lebanon County Medical Society was addressed in Lebanon recently by Dr. Franklin L. Payne, Philadelphia, on "Significance of Abnormal Vaginal Bleeding."—Lloyd M. Jones, professor of physical education, Pennsylvania State College, State College, addressed the Centre County Medical Society, Bellefonte, recently on physical fitness.

#### SOUTH CAROLINA

**State Medical Meeting in Columbia**—The ninety-fourth annual meeting of the South Carolina Medical Association will be held at the Columbia Hotel, Columbia, May 19-21, under the presidency of Dr. George M. Truluck, Orangeburg. The preliminary program lists the following speakers:

Dr. Vivian P. Patterson, Chester, General Practice in China  
Dr. William A. Smith, Charleston, Disseminated Circumscribed Pityriasis  
Dr. William L. Pressly, Due West, The Procurement and Management Service  
Dr. William Halsey Barker, Baltimore, The Sulfonamides  
Col. David N. Waller Grant, U. S. Army Medical Corps, Office Chief of Air Corps, Washington, D. C., Military Aviation  
Dr. Walter R. Mead, Florence, Diagnostic Significance of Various Types of Pain in the Back  
Dr. Dargun S. Pope Jr., and William A. Hart, Columbia, Treatment of a Pericardial Cyst  
Dr. Madison Hines Roberts, Atlanta, Graft Septic Membranes and Special Reference to Treatment of Influenza Membranes  
Dr. John J. Moorhead, New York, Experiences at Pearl Harbor

Mr. Joseph B. Hyde, Charleston, will be the exchange speaker of the South Carolina Pharmaceutical Association. The annual banquet will be addressed by Brig. Gen. Lewis B. Hershey, director, Selective Service System, Washington, D. C., Wednesday evening. The alumni luncheon of the Medical College of the State of South Carolina, Charleston, will be held on Wednesday afternoon at the Wade Hampton Hotel.

#### TENNESSEE

**Kellogg Foundation Grant to Meharry College**—A grant of \$250,000 has been given to Meharry Medical College, Nashville, by the W. K. Kellogg Foundation, Battle Creek, Mich., to finance an educational program in medicine, dentistry and nursing, newspapers announced on April 15. Fifteen thousand dollars will be made available annually for five years.

**Funds Approved for Hospital Construction**—The general assembly provided a bond issue of \$500,000, the proceeds of which are to be used for the construction of a tuberculosis hospital in Tennessee. The act providing the

authorizes the erection of a commission to make application for a grant of funds from the federal government to supplement the local funds and to select the location for the hospital.

**Changes in Health Personnel**—Dr Vernon W Foster, Savannah, Ga., has been placed in charge of the newly created health unit of Henry County. Dr Foster is on loan from the U S Public Health Service. Dr Horace M Roberson, health director for Bledsoe and Sequatchie counties, has been named to a similar position in Rhea and Meigs counties, succeeding Dr Hollis C Miles. Davton who resigned to return to private practice in Cincinnati, it is reported.—Dr Loyd D Farragut, Jackson, has resigned as director of the Madison County Health Unit to enter army service.

### GENERAL

**Dinner for Columbia Alumni at Atlantic City**—A dinner to be given by the alumni of Columbia University College of Physicians and Surgeons will be held Wednesday, June 10, at 7:30 p. m. at the Hotel Claridge, Atlantic City, rather than at 9 p. m. as was announced in THE JOURNAL, May 2, page 44.

**Tufts Alumni Meeting**—The secretary of the Tufts Medical Alumni Association, Dr Harry Blotner, Boston, writes that the Tufts medical alumni will hold their luncheon meeting at the Ambassador Hotel in Atlantic City, Wednesday, June 10, during the period of the annual session of the American Medical Association.

**Changes in Strength in Mercurial Ointments**—The Committee of Revision of the Pharmacopeia of the United States of America announces that certain changes have been made in the strengths of U S P mild mercurial ointment (blue ointment) and U S P ammoniated mercury ointment (white precipitate ointment). The change was made to conserve limited stocks of mercury on purely therapeutic grounds and was necessitated by war emergency conditions.

**New Bulletin on Science**—The executive committee of the American Association for the Advancement of Science has authorized the publication of an eight page monthly, *A A A S Bulletin*, to be edited by the permanent secretary, Forest R. Moulton, Ph.D., Washington, D. C. The new bulletin will be sent to each member of the association, the subscription price to be included in the annual dues. The association announces that the meeting planned during the week of June 22 at Ann Arbor has been canceled. However, the group will meet in New York on December 28.

**Officers of National Health Council**—Dr George S. Stevenson, medical director of the National Committee for Mental Hygiene, New York, has been elected president of the National Health Council to succeed Dr Kendall Emerson, managing director of the National Tuberculosis Association who becomes vice president and chairman of the executive committee. Other officers elected are Dr William F. Snow, general director of the American Social Hygiene Association, treasurer, and Mrs. Eleanor Brown Merrill, executive director of the National Society for the Prevention of Blindness, secretary.

**Accidental Deaths Increase**—Accidental deaths reported to workmen's compensation commissions in twenty-six principal industrial states totaled 8,381 in 1941 as compared with 7,732 in 1940. The largest increase was reported in Connecticut with 93 deaths in 1941 against 49 in 1940. Increases ranged downward from the Connecticut figures to 2 per cent for both Illinois and Minnesota. New York, one of the outstanding industrial states, recorded a 6 per cent drop. Other state commissions which received fewer reports of accidental deaths in 1941 were Georgia with a 7 per cent decrease, Vermont with a 14 per cent drop and West Virginia with a 15 per cent decrease.

**Yellow Fever Volunteer Dies**—John H. Andrus, who received congressional recognition for volunteering in the yellow fever experiments in Cuba in 1900-1901, died in the Naval Hospital, Philadelphia, aged 62. Mr. Andrus was one of a group of volunteers for experiments carried out under the late Drs. Walter Reed, James Carroll, Jesse W. Lazear and Aristides Agramonte. Mr. Andrus was a private in the hospital corps. He volunteered for the experiments and was infected with yellow fever at Camp Lazear by the injection of blood from a yellow fever patient. He became sick on Jan. 28, 1901, and was discharged on April 24, 1902. Congress in 1929 awarded him a gold medal and authorized a pension of \$125 a month.

**Academy of Tuberculosis Physicians**—The annual session of the American Academy of Tuberculosis Physicians will be held at the Hotel Dennis, Atlantic City, June 8-9 under the presidency of Dr. Oscar S. Levin, New York. The program will include the following speakers:

Dr. Leo L. J. Hardy, Chicago: Gastroscopic Findings in Far Advanced Pulmonary Tuberculosis.  
Dr. Morris Moore, St. Louis: The Chorioallantoic Membrane of Chick Embryos and Its Response to Inoculation with Some Mycobacteria.  
Dr. Samuel J. Hurwitz, San Francisco: Use of Gold Needle in Artificial Pneumothorax.  
Dr. Carl W. Tempel, major, U. S. Army, Washington, D. C.: Pneumoperitoneum: Its Place in Collapse Therapy.  
Dr. Zoltan Galambos, Chicago: Antituberculous Immune Substances in the Cellular Elements of the Blood in Arrested Pulmonary Tuberculosis.  
Dr. Jacob Werne, New York: A Study of the Frequency of Tuberculosis in a Population Dying of Violence.

**American Psychopathological Association**—The thirty-second annual meeting of the American Psychopathological Association will be held at the Hotel Statler, Boston, May 17-18, under the presidency of Dr. Roscoe W. Hall, Washington, D. C. Included among the speakers will be:

Dr. Lowell S. Selling, Detroit: Psychopathology and Nutrition.  
Dr. Edward J. Kempf, New York: The Significance of the Plasticity of Man for the Medical and Social Sciences.  
Dr. Helen Flanders Dunbar, New York: Personality Types Associated with Cardiovascular, Diabetic and Accident Syndromes.  
Dr. Bernard C. Glueck, Jr., Ossining, N. Y.: Psychopathological Reactions and Electric Shock Therapy.

The association will hold two joint sessions with the American Psychiatric Association on "Morale and Military Psychiatry" and "Psychiatry and the U. S. Navy." The annual dinner will be addressed by Ernest A. Hooton, Ph.D., professor of anthropology, Harvard University, Cambridge.

**Fatal Bicycle Accidents**—The Metropolitan Life Insurance Company has reported that about 1,100 persons were killed in bicycle accidents in 1941, nearly one fourth more than in 1940. About 900 lives have been lost through these accidents annually since 1936. In 1932, before the strong revival of recreational bicycling, there were only about 450 deaths. Of the 1,100 fatalities to cyclists last year, more than 900 resulted from injuries sustained in collisions with automobiles. Others were charged to falling off the bicycle, running into trees, curbs or other fixed objects and running into street cars. A number of pedestrians also were struck and fatally injured by bicycles. Among adult male insured persons between the ages of 20 and 64, the death rate in bicycle collisions with automobiles of 63 per million persons in 1941 was the highest in the seventeen years on which data are available. Each year boys in the age group of 10 to 19 are the most frequent victims. In the years 1936 to 1941 the annual death rate of bicycle-automobile collisions was 32.5 of insured boys from the ages of 10 to 19. Bicycle fatalities were relatively infrequent among insured girls and women.

**Ear, Nose and Throat Meeting**—The forty-eighth annual session of the American Laryngological, Rhinological and Otolaryngological Society, Inc., will be held at the Chalfonte-Haddon Hall, Atlantic City, N. J., June 1-3, under the presidency of Dr. James A. Babbitt, Philadelphia. Among the speakers will be:

Dr. George M. Coates, Philadelphia: The Nasopharynx.  
Dr. Paul A. Campbell, major, medical corps, Randolph Field, Texas: Otolaryngologic Problems of Aviation in World War II.  
Dr. Albert C. Furstenberg, Ann Arbor, Mich.: Neurologic Lesions Which Influence the Sense of Smell: A Clinical and Pathologic Study.  
Dr. Carl H. McCaskey, Indianapolis: Chronic Nonspecific Recurring Parotitis.  
Dr. Harrington B. Graham, San Francisco: Keratosis of the Larynx.  
Drs. Louis H. Clerf and Francis J. Braceland, Philadelphia: Functional Aphonia.  
Dr. Gordon B. New, Rochester, Minn.: The Treatment of Congenital Cysts of the Larynx.  
Drs. Samuel J. Crowe and John E. Bordley, Baltimore: The Use of the Sulfonamide Drugs and Gramicidin in Otolaryngology.  
Dr. Edmund P. Fowler, New York: Control of Head Noises: Their Illusions of Loudness and Timbre.

**War Production Fund to Conserve Manpower**—A group of leading corporation executives has organized the War Production Fund to Conserve Manpower under the auspices of the National Safety Council. According to a release the War Production Fund resulted from a proclamation of President Roosevelt calling on the National Safety Council to mobilize the nation's volunteer resources against a rising accident toll that last year claimed the lives of 101,500 persons, permanently disabled 350,000, injured 3,750,000 workers and deprived industry of 460,000,000 man-days of labor. Studies made by the National Safety Council indicate that industry was deprived by accidents of 10 per cent more man-days last year than in 1940, and the first month of this year showed a continuing rise as compared with the corresponding month of

1941 In twelve states the death toll from occupational accidents alone showed increases in 1941 ranging from 25 to 77 per cent. The new setup would work toward the installation of safety programs in many of the 171,000 industrial plants now lacking them and the nation's 15,000,000 industrial workers would be educated to safety. It is estimated that the expanded safety program will cost 5 million dollars and the War Production Fund has undertaken the responsibility of financing the project through enlisting the support of the nation's major industrial and business corporations. Mr. William A. Irvin, New York, director of the board of the U. S. Steel Corporation, is chairman of the War Production Fund.

**American Rheumatism Association**—The ninth annual meeting of the American Rheumatism Association will be held at Chalfonte-Haddon Hall, Atlantic City, N. J., June 8, under the presidency of Dr. Loising T. Swaim, Boston. The following program will be presented:

Drs. Paul L. Boisvert, New Haven, Conn., James D. Trask, New Haven, Martin Henry Dawson and Francis F. Schwenker, New York. Epidemic Rheumatic Fever.

Capt. Ruskin M. Lhamon, U. S. Navy, Lieut. Robert W. Huntington, Jr., U. S. Navy Reserve, Washington, D. C., Drs. Stafford M. Wheeler and Thomas Duckett Jones, Boston. An Epidemic of Hemolytic Streptococcus Infection and Rheumatic Fever Among Naval Trainees.

Dr. Granville A. Bennett, Boston. Comparison of the Pathology of Rheumatic Fever and Rheumatoid Arthritis.

Dr. Theodore B. Byles, Boston. Rheumatoid Arthritis and Rheumatic Heart Disease in a Series of Autopsied Cases.

Dr. Warren T. Vrugliun, Richmond, Va., Food Allergy as a Possible Factor in Subacute Recurrent Arthritis.

Drs. Alfred O. Ludwig, Charles L. Short and Walter Bruer, Boston. The Spinal Fluid Protein in Rheumatoid Arthritis.

Drs. Readie Garfield Snyder, Willard Haywood Squires, John Wilfrid Forster and Cornelius Horace Traeger, New York. The Treatment of Arthritis with an Agent Containing Massive Doses of Vitamin D.

Dr. John G. Kuhns, Boston. The Treatment of Arthritic Contractures of the Knee.

Drs. Edward T. Rosenberg, Archie H. Biggenstoss and Philip S. Hench, Rochester, Minn., An Analysis of the Manner of Death Among Thirty Patients with Rheumatoid Arthritis.

Dr. Charles L. Steinberg, Rochester, N. Y., The Tocopherols (Vitamin E) in the Treatment of Primary Fibrositis.

The annual dinner will be addressed by Brig. Gen. Charles C. Hillman, Washington, D. C.

**Meeting of Chest Physicians**—The eighth annual meeting of the American College of Chest Physicians will be held at the Hotel Dennis, Atlantic City, June 6-8, under the presidency of Dr. Benjamin Goldberg, Chicago. Among the speakers will be:

Drs. Raul F. Vaccarezza and Alvaro E. Bence, Buenos Aires, Argentina. Results Obtained from the Examination of Partitioned Lung Areas.

Dr. William A. Hudson, Detroit. Management of Pulmonary Cavities.

Dr. Hans E. Schiffrbauer, Los Angeles. Traumatic Rupture of the Diaphragm Simulating Pulmonary Tuberculosis. Transpleural Repair.

Drs. Chevalier L. Jackson and John Franklin Huber, Philadelphia. Applied Anatomy of the Tracheobronchial Tree and a System of Bronchial Nomenclature.

Dr. Robert W. Keeton, Chicago. Adequacy of Diabetic Management in the Presence of Infection.

Dr. Oscar Auerbach, New York. Pulmonary Tuberculosis Secondary to the Rupture of Cold Abscesses into the Lung.

Dr. Herman L. Kretschmer, Chicago. Diagnosis and Treatment of Renal Tuberculosis.

Military affairs will be discussed on June 7 by:

Brig. Gen. Charles C. Hillman, Washington, D. C., Tuberculosis in the Army.

Commander Robert E. Duncan, Washington, D. C., Tuberculosis in the Navy.

Dr. Roy A. Wolford, chief of the tuberculosis division, U. S. Veterans Bureau, Washington, D. C., Present Status of the Tuberculosis Problems in the U. S. Veterans Bureau.

Dr. Herman E. Hilleboe, passed assistant surgeon, U. S. Public Health Service, Washington, D. C., Tuberculosis Control in National Defense.

Dr. Esmond R. Long, Philadelphia. Relationship Between the National Research Council and Our Four Medical Services.

A joint session with the American Broncho-Esophagological Association will be held on June 8 with the following speakers: Drs. Paul H. Holinger, Chicago, on "Kodachrome Visualization of the Physiology and Pathology of the Tracheobronchial Tree", Louis H. Clerf and Carl J. Bucher, Philadelphia, "Adenoma (Mixed Tumor of the Bronchus)", Ralph C. Matson, Portland, Ore., "Bronchoscopic Aids in Chest Surgery" and Joseph W. Peabody, Washington, D. C., "Bronchoscopic Aids in Medical Conditions Within the Chest".

## LATIN AMERICA

**New Journal on Hygiene**—The *Boletín del Departamento de Higiene de la Provincia de Córdoba* has recently made its appearance. The first issues include original articles, excerpts from Brazilian lectures, a section on laws and miscellaneous articles covering hygiene and public health in Brazil. The headquarters of the new publication are at Boulevard Junin 507, Córdoba, Argentina.

**Honor Memory of Havana Physician**—On Sept. 22, 1941 a tablet was unveiled to honor the memory of the late Dr. Raimundo de Castro y Allo, professor of clinical medicine at the Faculty of Medicine of the University of Havana for twenty-five years. He was the head of the clinic of Hospital Mercedes for several years, president of various medical societies, delegate to several medical congresses and author of numerous articles and books. He died in 1902.

## FOREIGN

**British Medical Journal Comments on Paper Restriction**—The *British Medical Journal*, in a recent editorial comment, discusses the progressive limitation of the paper supply in relation to the gradually reduced size of the *Journal*. The editorial points out that the Scandinavian sources of material for paper making were cut off in April 1940. The continued drastic curtailment in paper rations will be met in the future by the printing of fewer pages and the use of smaller type. It is pointed out that "since this is a professional organ of information and opinion, owned by the members and not run for profit, the advertisement pages have to fare far worse under the axe than the editorial pages." The editorial reads in part as follows:

The British Medical Association, unlike the proprietors of all new papers and of most periodicals, cannot compensate for dwindling paper supplies by materially cutting down circulation because it is bound to send a copy of its *Journal* every week to each of the 40,000 members. Every effort will be made to economize space and to secure an adequate amount of paper, but readers and contributors must help us to make the best of a bad situation and be prepared for disappointments. The generous space given to correspondence will have to be curtailed which means fewer and shorter letters. Every one in these days is putting up with things he never thought to endure, and we look confidently to members of the B. M. A. to exercise forbearance. As for conciseness, it has become a major virtue in all who put pen to paper.

## Government Services

### Appointments in Hospital Service

Dr. Dean A. Clark, New York, U. S. Public Health Service, has been appointed head of the hospital section of the medical division of the Office of Civilian Defense and also head of the new emergency medical section in the public health service which will administer the hospital program jointly with the Office of Civilian Defense. *Modern Hospital* further reports that Mr. Harry N. Hooper, superintendent of Cincinnati General Hospital, has been granted a leave of absence to serve as consultant in hospital administration to the medical division.

### Dr. Turner Assigned as Chief of Venereal Disease Control

Dr. Thomas B. Turner, professor of bacteriology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, and lieutenant colonel in the medical reserve corps of the U. S. Army, has been called into active service as chief of the subdivision of venereal disease control in the surgeon general's office. He has been in charge of the division of venereal disease control at the school of hygiene and public health, where he was assigned as a staff member of the International Health Division of the Rockefeller Foundation. He graduated at the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1925. About 100 specially trained venereal disease control officers are being assigned as assistant to the surgeon in each army division, to each corps area and department, to each army headquarters, to general headquarters and to a camp of 20,000 or more troops to carry forward the comprehensive program to reduce loss of the army through venereal disease. In the civilian communities, the officers will cooperate with all agencies concerned with control of these diseases to insure the effective repression of prostitution and the adequate quarantine and treatment of infected civilians as a measure to prevent infection. Cooperation will be carried out with the Bureau of Medicine and Surgery of the U. S. Navy, the Social Protection and the U. S. Public Health Service of the Federal Government, the federal bureau of investigation, health enforcement agencies of states and smaller political divisions, and certain unofficial agencies such as the American Social Hygiene Association, according to *Social Hygiene News*.

### LONDON

(From Our Regular Correspondent)

March 28, 1942

#### More Men, Women and Physicians Called Up

The operation of the national service acts has been extended to men from the age of 18 to those who have not reached 46 and to women who have reached the age of 21 but not that of 31. Previously the higher age limit for men was 41. Women are joining in the war effort to such an extent that already five million are registered. They are employed in services auxiliary to the fighting forces, in munition works, in nursing and welfare work, in civil defense and in other services required in the war effort. Girls of 16 and 17 are shortly to be registered under a youth scheme and those of 18 and 19 for purposes of record in order to complete the picture of our woman power, which is being mobilized on a scale hitherto unparalleled.

The women of the country, as well as the men, are now conscripted. The first medical examination of women conscripts has been held at four London centers. The women were all in the 20-21 age group. Most of them will be enrolled for auxiliary military service. They were placed in four grades: 1. Fit in every way. 2. Fit, but not for strenuous work. 3. Not fit for uniformed service but liable for civilian work of national importance. 4. Completely unfit. Most of the girls were placed in the first two grades. They were examined by three physicians (two men and one woman). Each had the right to claim examination by a woman only, but this was seldom done. The medical examination was thorough.

It is found necessary to extend the field for the recruitment of physicians and dentists, additional numbers of which are required in the armed forces. The arrangements which exist for their recruitment below the age of 41 are to be extended to 46. Each case will be reviewed by the Central Medical War Committee or the Dental War Committee and their local committees, which take into account the needs of both armed forces and the civil population.

#### Precautions Against Typhus Fever

On the continent of Europe typhus has proved a war scourge but so far has not spread to Britain. Elaborate precautions, however, are being taken. At the suggestion of the Ministry of Health the authorities in London have arranged the measures to be taken in case of an outbreak. The London County Council has provided for the use of one of its hospitals. Five London southwestern boroughs have drawn up a joint plan. As a preliminary twelve members of the Kensington public health staff have been immunized against typhus, protective clothing has been provided and they are being trained in dealing with clothing from typhus patients and with contacts. Kensington already has the plant for the delousing of furniture and clothing. If a case of typhus is diagnosed the health officer will immediately order the necessary measures. A van manned by a team wearing protective clothing will go to the house and remove bedding and clothing in stout bags, and the premises will be fumigated. Contacts will be deloused and taken in special transport to a delousing station. To prevent the introduction of typhus into the country a close watch is kept by health officers at ports and airports. Special mobile diagnostic and sanitary teams are being trained and organized. Arrangements for confirmatory diagnosis by experts have been made. Plans similar to those described have been made by other local health authorities for prompt isolation, hospital treatment and disinfection. Finally there is a general intensification of delousing and cleansing of verminous conditions for which local authorities have been given additional powers.

#### The Problem of Feeding Europe After the War

Dr Geoffrey Bourne of the University Laboratory, Oxford, discusses in a recent issue of *Nature* the question: What foods should be held ready to rush to Europe after the war? All the occupied countries, as well as the belligerents, are rationed. In some the bread ration is high: 80 ounces a week in Germany and 85 ounces in Denmark. In others the ration is low: 50 ounces in Italy, 55 in Belgium, 30 in Greece. Starvation must occur unless the deficiency is made good by other foods. Thirty ounces of bread a week provides only 300 calories a day. If there are not other foods to supply the calories, the position is serious. One way is by fat and potatoes. But in most of the countries fats are rationed and in some potatoes. In Belgium and Italy the fat ration is very low:  $3\frac{1}{2}$  ounces a week, in France it is 4 ounces. In view of the deficiency of calories, the French were urged to drink more wine. But they did this to such effect that wine is now rationed. The following estimates have been made of the number of calories per head available daily: Germany 2,900, Norway 2,500, Italy 2,400, Bohemia 2,300, unoccupied France 2,160, occupied France 2,100, the Netherlands 2,250, Belgium and Luxembourg 1,870. Figures cannot be given for Greece and Poland but the conditions are known to be very bad. The foregoing figures are probably optimistic.

Food also is deficient in quality. There is deficiency of protein and vitamins, which will probably have a serious effect on growing children. The decrease in the consumption of milk, cheese and butter means a reduction in the supply of vitamins A and D and riboflavin. Restriction of fruit means deficiency of vitamin C unless compensated by vegetables. Norwegians, Greeks and Poles are probably suffering from a mild form of scurvy. At the end of the war Europe will probably suffer from an absolute lack of food and deficiency of first class protein, vitamins A, C and D and calcium.

Dr Bourne recommends wheat as the first food to be rushed to Europe after the war and dried milk, whole or skimmed as the second. As dried whole milk does not keep well it would be better to supply dried skimmed milk and turn the fat into dehydrated butter, which keeps well. As supplies of these foods will probably be insufficient, there should be ready a store of extra fats such as whale oil, and of protein in the form of dried meat and fish. Soya bean flour could also be stored for adding to wheat flour to augment the protein value of the bread. Synthetic vitamin C or citrus fruit concentrate also should be supplied. Second, we must plan for the continued feeding of Europe, which means planning not only of European but of world agriculture. This was discussed by the agriculturist Sir John Orr at the British Association Conference of 1941.

#### Reform in Teaching Anatomy

It is the experience of most medical practitioners that at their medical schools they were taught many details of anatomy which they have long forgotten. Five teachers of anatomy have published in the *British Medical Journal* a joint letter on the subject. They say that the usual curriculum of anatomy is partly determined by ideas no longer valid. Much is concerned with topographic details important only to the surgical specialist. A curriculum should be planned to provide the best possible education for the general practitioner. Such a training should provide a sound educational approach to any branch of anatomy and a foundation on which the minutiae of applied anatomy for clinical specialization can be built up at a later stage in special courses of instruction. It is far more important that a student should be well acquainted with general anatomic principles than that he should memorize facts of which a large proportion are likely to be of no practical value. Anatomic teaching must cover the whole realm of macroscopic and microscopic structure and for the proper comprehension of structural organization histology should be taught in direct relation to the study of

gross structure and of embryology and histogenesis. Embryologic study should direct attention to morphogenic mechanisms rather than to the descriptive details of developmental stages. Great importance should be attached to courses of instruction, combined with practical study on general principles of structural organization, with special reference to processes of tissue differentiation, growth and repair, structural adaptation in response to functional requirements, and the influence of mechanical, hormonal and other factors in the induction of structural modifications. It has been shown in some schools that courses can be so arranged that all students in the same year study the same part of the body at the same time. Lectures on the anatomy of the living body, radiologic anatomy, histology and embryology can then be planned so as to deal with the part which is being dissected, allowing a much clearer correlation than in the usual curriculum. Lastly, students should be given more instruction on the postnatal growth of the body and its relation to nutritional, hormonal and other factors. A course of lectures on human genetics would be an appropriate sequel to embryology.

#### Wheat for the Starving Greeks

In the House of Commons, Mr Dalton, minister of economic warfare, stated that the government had always refused to allow foodstuffs to be shipped through the blockade and thus relieve the enemy of the responsibility for feeding the peoples whom he had enslaved. But the governments of Britain and the United States had viewed with increasing dismay the appalling conditions in Greece. Despite the ability to do so, the German government had done practically nothing to meet the situation created by the pillage and extortion of its armies in the spring of 1941. Britain and the United States were prepared to authorize the shipment of 8,000 tons of wheat to Greece to be applied under the auspices of the International Red Cross in relief of the present emergency. This is in addition to the permitted shipments from Turkey of foodstuffs. The governments of Britain and the United States continue to maintain that it is incumbent on the enemy to feed the occupied countries.

#### The Bread Controversy

There was no shortage of bread, but eggs, fish and winter supplies of milk were short. Referring to wholemeal bread, increasing the extraction of flour to 85 per cent saved shipping and had nutritive advantages but reduced the supply of animal feeding stuffs and thus of milk, meat and eggs. In the debate Sir Ernest Graham-Little (dermatologist) stressed the value of wholemeal bread, of which he has been the leading propagandist since the subject has become topical. Sir William Bragg (ex-president of the Royal Society) had said that we should go back to it. It contained twice as much iron as white bread, ten times as much vitamin A and three times as much vitamin B. Graham-Little attacked the expensive project of the government to vitaminize white bread. He did not think that the people would resent compulsion to eat whole wheat, which was more nutritious and would save shipping. There was anxiety in the medical profession at the incidence of deficiency diseases. The wholemeal loaf was discredited because its production to specification was not enforced. The production of white bread should be prohibited.

#### Medical Relations with Russia

The struggle of Russia against the invaders has aroused admiration in this country and movements to help in every possible way. The Red Cross fund raised by Mrs Churchill now exceeds \$7,500,000. A committee presided over by Sir Alfred Webb-Johnson, president of the Royal College of Surgeons, for providing surgical instruments has met with a good response. Instruments valued at \$15,000 have been sent by donors who

do not require or can spare them. The instruments were in such good condition that less than 10 per cent required repair. For the purchase of medical supplies a subcommittee is advising Mme Maiskiy, wife of the ambassador. During the last three months x-ray sets, autoclaves and other equipment have been sent in seventy large cases, some weighing a quarter of a ton. For the committee a book reviewing British war medicine is being compiled by Sir Philip Manson-Bahr and Mr G F Home and is being translated into Russian by physicians who have volunteered for the work.

#### Arthroplasty of the Hip Joint

At the annual meeting of the British Orthopedic Association Prof P D Wilson of New York reviewed the history of arthroplasty of the hip joint and dealt with the two methods now employed: fascial interposition with a history of twenty years and vitalium cups with a history of three or four years. He reported 39 cases, in which 45 arthroplasties had been performed, of which he had followed up 41. Of these fascial implantation was performed in 12 and the cup method in 28. In both forms of operation the best results were obtained when there was solid bony ankylosis. Periarticular scarring and adhesions were less than when there was fibrous ankylosis. Statistics tended to show a slightly better result from fascial interposition, but this was counterbalanced somewhat by the simpler technic and easier recovery when vitalium cups were used. Poor results with these occurred largely in the group of arthritic patients. The best results were obtained in conditions the result of trauma or septic necrosis. By means of the vitalium cup a wider range of use was established in old unreduced congenital dislocations.

#### Society for the Study of Child Health

A number of health officers and others have sent a letter to the *Times* stating that it has become evident that present knowledge of the factors affecting child health and our present means for maintaining it are inadequate. They think the time is ripe for the formation of a planning group in this branch of applied medicine. The object would be to study child health and explore the possibilities of improving the general health of children, with particular regard to social and environmental factors, nutrition and the better organization and coordination of agencies for child care. Such a group would be organized on regional lines so as to facilitate the meeting of members for discussion and would have a central body to correlate the findings and suggestions of the subgroups. Membership would not be confined to the personnel of the health services but would be open to all actively concerned with or interested in the objects of the group, including private physicians, dentists, teachers, nurses and students. No society of this kind has ever existed before, though it might be claimed that the subject comes within the scope of the Section for the Study of Disease in Children of the Royal Society of Medicine. But there the standpoint is that of the pediatrician, while here it is that of the health officer and the field is narrowed to prevention.

#### Psychologic Testing for the Army

A new development in the army is the General Service Corps, in which recruits undergo their basic training and the corps for which they are best suited is determined. The main factors are physical health, general intelligence, special aptitudes and a standard of attainment, which are all tested. The most difficult factor to assess is personality, but it is hoped to devise a test for this. A directorate of personnel selection has been set up and it is assisted by an advisory committee of psychologists, composed of Prof J Bever, Dr C S Myers, Prof I G Bartlett and Prof C L Burt. Care was taken to try out tests against practical results before they were introduced. The

recruits for an armored formation were tested and a list was made of the men found unsuitable for service with tanks. After three months the list was compared with practical experience and found to agree within 5 per cent of error.

There are three filters. First a general intelligence test is given on recruiting, second, during training misfits are combed out and transferred, third, the men most suitable for training as officers are sifted out. The last is based to some extent on German experience and is directed to ensuring that a leader is more intelligent and has quicker reactions and more personality than his men. Education and book knowledge play only a small part in intelligence tests, which are directed to determining the mother wit of the recruit. For example he is given a book containing a series of diagrams from which a section has been removed and he is asked to complete them from a number of alternatives.

### BUENOS AIRES

(From Our Regular Correspondent)

March 15, 1942

#### The Chair of History of Medicine

The Chair of History of Medicine of the Faculty of Medical Sciences of the University of Buenos Aires was established in 1937 with Dr. Juan Ramon Beltran as professor. Dr. Beltran wrote a book on the first medical society of Argentina and published it before the chair was established. The society was formed during the last few years of the colonial period. It was made up of physicians who organized the work to be carried on for the general care of the sick in hospitals and in towns with a large number of soldiers and who were regarded as the highest authorities of the country in administration of health and hygiene. The most important aims of Dr. Beltran and his group are (1) to have complete records of the development of medical history in Argentina with monographic and bibliographic data of all those who were concerned with it, (2) to organize an index with biographic and bibliographic data of Argentinean pioneers and of workers on medicine during the last few years and (3) to organize a museum for the history of medicine. Some of the work of the chair has been published during the last few years in four volumes which were issued with the name of 'Publicaciones de la Catedra de Historia de la Medicina'. The volumes contain historical studies and research by well known Latin American historians. Volume 2 contains articles by Beltran entitled 'Introduccion al estudio de la historia de la Medicina', 'Sintesis historica de la Academia Nacional de Medicina de Buenos Aires', 'Estudios especiales sobre el Colegio de San Fernando de Lima' and 'Epistolario of Miguel Gorman' who was the most popular physician of the first medical society of La Plata. Some important articles in the other three volumes are 'La medicina entre los Mayas' by Maximo Soto Hall, 'Historia de la anestesia' by Marquez Miranda, 'La fundacion de la Casa de Expositos' by Alonso.

La organizacion colonial del hospital de mujeres en Buenos Aires by Anibal Ruiz Moreno and articles on the work carried on by Ramon y Cajal by Ara, on the work carried on by Semmelweis by Beruti on epidemics in Buenos Aires by Besio Moreno and on the work carried on by Nicolas Monardes by Torres Revello. The collection of articles in these volumes is of great importance.

#### New Journal on History of Medicine

The first issue of the *Revista Argentina de Historia de la Medicina* which is the official organ of the society Ateneo de la Historia de la Medicina of Buenos Aires, was dated January 1942. It contains the following articles: 'Primeros Estudios de Medicina en Cuba' by Horacio Abascal, 'Rosas el Dictador en Argentina' by Beltran and 'Historia de la Medi-

cina en Argentina' by Sigerist. It contains also an article on 'Jade of China' by Juan Marin and several commentaries and notes on the history of medicine. This journal will appear three times a year.

### Personals

The society Ateneo de Historia de la Medicina of Buenos Aires recently appointed as honorary members Tricot Roger, founder and honorary president of the International Society of the History of Medicine, Laignel-Lavastine of the Faculty of Medicine of Paris, Paul Diepgen of the University of Berlin, Esmond R. Long, president of the American Association of the History of Medicine, Prof. Henry E. Sigerist of the Johns Hopkins University School of Medicine, Carlos Enrique Paz Soldan of the University of San Marcos, Lima, Juan B. Lastres of the Faculty of Medicine of Lima, Gregorio Marañon, noted for Spanish researches on endocrinology, Carlos Martinez Duran of Guatemala, Alfonso Pruneda of Mexico, Horacio Abascal of Havana, Alfredo Monteiro, Mariano de Andrade, Raul Jobin Bittencourt and A. Barboza Viana of Rio de Janeiro, Raul Briquet, Edmundo Vasconcelos and Alvaro Guimaraes Filho of São Paulo, Brazil, Raul Laitao da Cunha, dean of the National University of Rio de Janeiro, and Jose Arce, ex-dean of the Faculty of Medical Sciences of Buenos Aires.

### BUCHAREST

(From Our Regular Correspondent)

Dec 27, 1941

#### Precautionary Measures Against Foot and Mouth Disease

Although foot and mouth disease has not been reported in this country for a long time, the Ministry of Health addressed a circular to all sanitary authorities pointing out that the disease appears to have been introduced in the past through private slaughter houses in which the disease was not recognized. Not only the slaughter house was involved but all places where the meat from it was deposited, prepared or exposed for sale. The parts of the animals requiring special examination are the head, tongue and feet. Cattle, sheep, goats and pigs may be affected and the disease is transmissible to human beings to whom, however, danger to life therefrom occurs only in exceptional cases. The disease in animals is compulsorily notifiable to the police—in villages to the district veterinary surgeon whose duty it is to pass the notification to the competent authorities. The disease may be transmitted to man through milk, butter and cheese or by inoculation through wounds in the hands and arms and may cause in man fever and digestive troubles, vesicles on the lips, fingers, arms, inside the mouth, pharynx and conjunctivas, salivation, nausea, offensive breath, pains in the limbs and swelling of the cervical glands. The technical name of the disease is epizootic eczema and the virus appears in concentrated form in the vesicles and saliva of those affected.

A special circular was sent to medical officers of health and to parish physicians with instructions as to isolation, differential diagnosis and treatment. The circular describes a case in which the infection of foot and mouth disease was localized to the eye. In this case contact was by shaking hands. Conjunctivitis developed and severe ciliary injection followed. The cornea was free. The inner third of the superior palpebral margin suppurated and was covered with a semiaherent membrane. Both eyelids were considerably edematous and there were large firm, slightly sensitive glands below the angle of the chin and in the neck. Treatment consisted of local applications of mercuric bichloride 1:4000 and 2 per cent preparation of colloidal silver and silver oxide stabilized by derived egg albumin (collargol) administered almost every hour. Within eight days the eyes and mouth healed as well as the cutaneous nodules. Recovery was complete.

## Deaths

**Shirley Wilmotte Wynne**, New York, Columbia University College of Physicians and Surgeons, New York, 1904, medical inspector, city department of health, from 1907 to 1911, assistant registrar from 1911 to 1915, chief of the division of statistical research from 1915 to 1920, assistant to the commissioner of health from 1920 to 1924, director of hospitals from 1924 to 1926, deputy commissioner from 1926 to 1928 and commissioner of health from 1928 to 1933, formerly professor of preventive medicine, New York Polyclinic Medical School and Hospital, consulting physician Willard Parker Hospital and the Midtown Hospital, at one time trustee of the New York State Hospital for Incipient Tuberculosis, Otisville, N Y, president of the Children's Welfare Federation, aged 59, died, April 19, in St Luke's Hospital of acute appendicitis with peritonitis

**Frank Breckenridge Earle**, La Grange, Ill, College of Physicians and Surgeons of Chicago, 1885, member of the Illinois State Medical Society, joined the staff of his alma mater in 1885 with the title curator of museums, in 1888 became lecturer on practice of medicine, in 1889 assistant to the chair of practice, in 1894 lecturer on obstetrics, from 1895 to 1902 professor of obstetrics, from 1901 to 1913 secretary of the college, and from 1903 until September 1914 professor of pediatrics, when he was made professor emeritus, served during World War I, aged 81, died, March 6, in Eustis, Fla, of arteriosclerosis and bilateral pyonephrosis

**Edwin Abe Baumgartner** Ⓢ Newark, N Y, Washington University School of Medicine, St Louis, 1919, member of the American Association of Pathologists and Bacteriologists, fellow of the American College of Physicians, instructor of anatomy at the University of Wisconsin, Madison, 1911-1912, University of Minnesota, Minneapolis, from 1912 to 1914 and instructor and later associate in anatomy at his alma mater from 1914 to 1919, associate pathologist, Clifton Springs (N Y) Sanitarium from 1921 to 1932, since 1932 director, Newark State School and county laboratory, aged 54, died, March 15, in the Clifton Springs Sanitarium of a streptococcal infection

**Ralph Merle Carter** Ⓢ Green Bay, Wis, Rush Medical College, Chicago, 1908, past president of the State Medical Association of Wisconsin, member of the Western Surgical Association, Clinical Orthopaedic Society, American Academy of Orthopaedic Surgeons and the American Association for the Surgery of Trauma, fellow of the American College of Surgeons, served during World War I, attending orthopedist, St Vincent's, Bellin Memorial and St Mary's hospitals, aged 58, died, March 24, of coronary thrombosis

**Henry George Lampe**, Chicago, College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1901, was associated with the Veterans Administration, Hines, Ill, from July 1923 to March 1928, formerly local surgeon, health officer and assistant surgeon, Illinois Central System, served during World I, aged 62, on the staff of the Illinois Central Hospital, where he died March 5, of coronary thrombosis and hypertensive heart disease

**Hallward Martin Blegen** Ⓢ Warren, Minn, University of Minnesota College of Medicine and Surgery, Minneapolis, 1909, past president of the Red River Valley Medical Society, surgeon for the Great Northern and Soo railways, coroner of Marshall County, president of the Warren board of education for twenty years, on the staff of the Warren Hospital, aged 56, died, March 26, in the University Hospital, Minneapolis, of Addison's disease

**Walter Erastus Spicer**, Jackson, Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884, member of the Michigan State Medical Society, formerly on the staff of the Manhattan Eye, Ear and Throat Hospital, New York, and the Children's Hospital, Randall's Island, N Y, aged 86, died, March 8, in the W A Foote Memorial Hospital of a fractured hip received in a fall on an icy sidewalk

**Maurice Duane Bird** Ⓢ Marinette, Wis, Rush Medical College, Chicago, 1896, formerly secretary of the Marinette-Florence Counties Medical Society fellow of the American College of Surgeons, consulting surgeon St Joseph's Hospital,

Menominee, Mich, on the staff of the Marinette General Hospital, served as surgeon for the Chicago, Milwaukee, St Paul and Pacific Railroad, aged 69, died, March 13, of heart disease

**George Artemas Brown**, Barre, Mass, College of Physicians and Surgeons, medical department of Columbia College, New York, 1883, member of the Massachusetts Medical Society and the New England Society of Psychiatry, physician and owner of the Elm Hill School for Feebleminded for many years, for many years member of the school committee, aged 83, died, March 14, of chronic myocarditis

**Ralph Ellis Murrell** Ⓢ Lieutenant Colonel, M C, U S Army, Washington, D C, St Louis College of Physicians and Surgeons, 1917, entered the medical corps of the U S Army as a first lieutenant Oct 31, 1919, served during World War I, was commissioned a captain May 5, 1921, a major May 7, 1930 and a lieutenant colonel May 7, 1938, aged 50, died, February 2, of cerebral hemorrhage

**Harry Fletcher White** Ⓢ Medical Director, U S Public Health Service, New York, University College of Medicine, Richmond, Va, 1908, was commissioned an assistant surgeon in the U S Public Health Service in 1913, passed assistant surgeon in 1917, surgeon in 1921, senior surgeon in 1933 and medical director since 1939, stationed at Ellis Island, N Y, since 1937, aged 57, died, January 23

**William Creighton A Garvin** Ⓢ Binghamton, N Y, Columbia University College of Physicians and Surgeons, New York, 1903, member of the American Psychiatric Association and the American Psychopathological Association, superintendent of the Binghamton State Hospital, formerly superintendent of the Kings Park (N Y) State Hospital, aged 68, died, April 3, of cerebral thrombosis

**Heber J Sears**, Salt Lake City, Harvey Medical College, Chicago, 1905, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906, member of the Utah State Medical Association, formerly professor of hygiene and sanitation at the University of Utah School of Medicine, aged 80, died, February 24, in Beverly Hills, Calif, of acute dilatation of the heart

**Robert Robinson Armstrong**, Passaic, N J, University of the City of New York Medical Department, New York, 1895, member of the Medical Society of New Jersey, served during World War I, surrogate of Passaic County, formerly member of the city board of health and board of education, at one time county physician, aged 69, died, April 6, of carcinoma of the mouth

**Max Robert Dinkelspiel** Ⓢ New York, Jefferson Medical College of Philadelphia, 1902, associate editor of the *Merck Manual of Therapeutics* and *Materia Medica*, at one time on the editorial staff of the *Philadelphia Medical Journal* and *Therapeutic Monthly*, translator of several volumes of Nadel's series of medicine, aged 66, died, March 13, of coronary heart disease

**Charles W Moseley**, Greensboro, N C, Baltimore Medical College, 1893, member of the Medical Society of the State of North Carolina, aged 76, on the staffs of the Wesley Long, St Leo's, L Richardson Memorial and Sternberger hospitals, charter member of the staff of the Piedmont Memorial Hospital where he died, March 7, of pneumonia

**Henry Woodul Smith**, Roodhouse, Ill, College of Physicians and Surgeons of Chicago, 1894, member of the Illinois State Medical Society, formerly member of the state legislature, at one time mayor and member of the board of education, aged 75, died, March 12, in Our Saviour's Hospital, Jacksonville, of carcinoma of the liver

**John Henry Rosenberg**, Prineville, Ore, University of Oregon Medical School, Portland, 1897, member of the Oregon State Medical Society, mayor of Prineville, served during World War I, formerly member of the state board of health, aged 67, died, February 24, in St Charles Hospital, Portland, of coronary embolus

**Henry S Stearns**, New York, University of the City of New York Medical Department, New York, 1884, member of the Medical Society of the State of New York, in 1905 president of the Medical Society of the County of New York, aged 80, died, April 2, of senility

**Joseph Warrick Clifford** Ⓢ Worthington, Ind, Graduate College of Eclectic Medicine and Surgery, Atlanta 1892, Affiliate Fellow of the American Medical Association, at one time county coroner, aged 79, died, March 26, in the Methodist Hospital, Indianapolis

George Boyd Dyche, Wheaton, Ill., Northwestern University Medical School Chicago, 1897, formerly associate professor of medicine at his alma mater, at one time on the staff of the Community Hospital, Geneva, aged 69, died, March 16, of carcinoma of the colon

Howard Russell Hansell, Sharon, Conn., University of Pennsylvania School of Medicine, Philadelphia 1927, member of the Connecticut State Medical Society, on the staff of the Sharon Hospital, aged 40, died, March 6, of acute myocarditis and arteriosclerosis

Hugh Ratcliffe Inksater, Calgary, Alta., Canada, University of Toronto Faculty of Medicine, 1930, was called to active duty as a captain in the Royal Canadian Army Medical Corps July 8, 1941, aged 35, was killed in an accident, January 18 while overseas

James Arnold Bledsoe, Port Arthur, Texas, University of Louisville (Ky.) Medical Department 1915 served with the British government during World War I and was awarded the Distinguished Service Cross, aged 53, died, March 7, of heart disease

Harry Randolph Spickhermon, North Henderson, Ill., College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois 1898, aged 68, died in March at St Mary's Hospital, Galesburg, of pneumonia and emphysema

Emanuel Taft @ Chicago University of Illinois College of Medicine Chicago, 1932 formerly on the staff of Mount Sinai Hospital, on the visiting staff of the Lutheran Deaconess Hospital, aged 33, died, March 1, in the Michael Reese Hospital

Waldemar Alfred Christensen, San Francisco, Kentucky School of Medicine Louisville 1896, formerly first lieutenant in the medical reserve corps of the U. S. Army, aged 71, died February 6, of coronary sclerosis and hypertrophy of the prostate

Anthony John Boucek, Pittsburgh, Western Pennsylvania Medical College, Pittsburgh 1890, member of the Medical Society of the State of Pennsylvania on the staff of St John's General Hospital, aged 73, died March 8, of coronary heart disease

Edward Miers @ Des Plaines Ill. Kentucky School of Medicine Louisville, 1905, National Medical University, Chicago 1907, on the staff of St Mary of Nazareth Hospital, Chicago aged 65 died March 14 of heart disease

Ernst Lohnberg @ San Francisco Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät Bonn Prussia Germany, 1911, aged 57, died February 14 of cerebral hemorrhage and hypertensive cardiovascular disease

Paul Menken Eicks, Grenloch N. J., University and Bellevue Hospital Medical College New York 1927 resident physician on the staff of the Camden County Hospital, aged 40 died March 6 of diabetes mellitus

Howard Draper Speakman, Pau France University of Pennsylvania Department of Medicine Philadelphia, 1881 formerly on the staff of the Manhattan Eye and Ear Hospital New York, aged 83 died March 9

Manfred Mayer Zachart, New York, Friedrich-Wilhelms-Universität Medizinische Fakultät Berlin Prussia, Germany, 1922 member of the Medical Society of the State of New York aged 46, died February 17

John Knox McLeod, Sydney, N. S. Canada Bellevue Hospital Medical College, New York 1883, served during World War I for many years medical health officer of Sydney aged 78 died February 19

Emery Wilbur Brooks, Muncie, Ind. Barnes Medical College St Louis 1901 served during World War I, aged 66 died March 30 in the Veterans Administration Facility Marion of cerebral hemorrhage

S. Clarence Swartz, Philadelphia Hahnemann Medical College and Hospital of Philadelphia 1909 on the auxiliary staff of the Sacred Heart Hospital, Allentown Pa., aged 57, died March 9, of heart disease

Axel Thorsten Larson, Chicago Northwestern University Medical School Chicago 1925 member of the Illinois State Medical Society aged 58 died March 14, in Tucson Ariz., of rheumatic heart disease

George Leonard Haefele, Cleveland Western Reserve University Medical Department, Cleveland 1885, served during World War I, aged 78, died, February 13, of cerebral hemorrhage and arteriosclerosis

George Herman Tuttle, South Acton Mass. Harvard Medical School, Boston, 1891, member of the Massachusetts Medical Society, aged 76, died, April 2, in the Massachusetts General Hospital, Boston

Ernest A. Dieckmann, Keosauqua, Ill., Missouri Medical College St Louis 1897 aged 73, died, March 10, in the Alton (Ill.) State Hospital of cerebral arteriosclerosis and fracture of the neck of the femur

John Morris Markley, Schwenkville, Pa., University of Pennsylvania Department of Medicine, Philadelphia 1898, member of the Medical Society of the State of Pennsylvania, aged 71, died, March 15

James Leon Harrington, Amherst, Mass., Jefferson Medical College of Philadelphia, 1903, member of the New England Dermatological Society, aged 63, was found dead March 3, in a hotel at Boston

Robert Weber, Yorktown, Ill. College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907, aged 64, hanged himself in February while in Los Angeles

Jefferson Davis Bradfield, Washington, D. C., Georgetown University School of Medicine, Washington 1891 formerly diagnostician in the District health department, aged 74, died, March 7

Harry Miller Anderson, Allentown, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1898, served during World War I, aged 65, died, March 3, of myocarditis

William Janowski Bernis, Buffalo, Harvard Medical School, Boston, 1907 member of the Association for Research in Nervous and Mental Diseases, aged 66, died, March 3 of myocarditis

John William Thomason @ Huntsville, Texas University of Virginia Department of Medicine Charlottesville 1885, fellow of the American College of Surgeons, aged 77, died, March 4

Mark Allen Gier, Elgin Ill., Jenner Medical College Chicago 1909, served during World War I, formerly on the staff of St Elizabeth Hospital, Chicago, aged 65, died, March 2

Julius Bernard Nelson, Long Beach Calif., St Louis University School of Medicine 1904, veteran of the Spanish-American War and World War I, aged 71, died, February 1

Evan Moody Gavin, Stafford Springs, Miss. University of Alabama School of Medicine 1910, state senator, served during World War I aged 55, died March 18, in Jackson

Thomas Hiller Dreher, St Matthews S. C. College of Physicians and Surgeons Baltimore 1891, aged 80, died, March 1 in the Tri-County Hospital, Orangeburg of uremia

Francis Xavier McNamara, Cleveland, Cleveland Medical College, 1897 University of Wooster Medical Department Cleveland 1904, aged 67 died February 24, of angina pectoris

Edward Whittier, Albion N. Y., University of Buffalo School of Medicine, 1889 aged 76 died March 9 in the Arnold Gregory Memorial Hospital of coronary occlusion

Frank J. Robinson @ Fairfield, Maine Long Island College Hospital Brooklyn 1875, an Affiliate Fellow of the American Medical Association aged 92, died, February 14

William Chahan, Springfield Mass. Johns Hopkins University School of Medicine Baltimore 1935 aged 32, was found dead in bed March 10 in a hotel in Allentown Pa.

John J. Kiefer, Westpoint Neb. St Louis College of Physicians and Surgeons 1897 aged 72 died February 16 in the St Joseph Home and Hospital of heart disease

Curt H. Weis, Lampas Idaho Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät Bonn Prussia, Germany 1938 aged 33 died recently in San Francisco

William Michael Maloney @ Los Angeles Cornell University Medical College New York 1924 on the staff of the Queen of Angels Hospital aged 61 died February 28

Ernst Steinitz @ New York Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät Breslau Prussia Germany, 1904 aged 60 was found dead February 1

**Charles Fremont Turney**, Columbus, Ohio, Starling Medical College, Columbus, 1880, formerly member of the city council and school board, aged 85, died, February 20

**John Henry Meyhaus**, Sioux City, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900, aged 69, died, March 6

**Harry Cockerille Blair**, Elkins, W Va, University of Louisville (Ky) Medical Department, 1911, served during World War I, aged 56, died in March

**William Joseph Riordan**, Wallingford, Conn, Baltimore Medical College, 1909, member of the Connecticut State Medical Society, aged 56, died in March

**Joseph Burch Davis**, Huntington Park, Calif, Chicago Homeopathic Medical College, 1894, aged 72, died, February 10, of coronary heart disease

**Henry Roland Niles**, Los Angeles, Detroit College of Medicine, 1894, aged 72, died in February of carcinoma of the ureter and cirrhosis of the liver

**Frank Oscar Burk** Ⓢ Davenport, Iowa, State University of Iowa College of Medicine, Iowa City, 1907, aged 67, died, March 10, in the Mercy Hospital

**Thomas P Bodkin**, San Francisco, Cooper Medical College, San Francisco, 1893, aged 74, died, February 26, of nephrosis and coronary sclerosis

**Oscar Clarence Kessler**, Elkland, Mo, Ensworth Medical College, St Joseph, 1888, aged 82, died in February at a hospital in Springfield of nephritis

**Rex Lewis Ross**, Santa Monica, Calif, Jefferson Medical College of Philadelphia, 1916, served during World War I, aged 56, died, February 9

**Samuel D Houston** Ⓢ Polo, Ill, Chicago Physio-Medical Institute, 1886, aged 84, died, March 10, in the Hinsdale (Ill) Sanitarium and Hospital

**William Henry Peer**, Flushing, N Y, University of the City of New York Medical Department, New York, 1888, aged 74, died, February 22

**James Jorgen Clausen**, Kansas City, Mo, College of Physicians and Surgeons of Chicago, 1891, aged 76, died, March 4, of carcinomatosis

**Ford Nelson Jones**, New Orleans, University of Michigan Homeopathic Medical School, Ann Arbor, 1908, aged 59, died, March 4, of heart disease

**Frank Charles Baecht**, Grafton, Ill, Beaumont Hospital Medical College, St Louis, 1895, served during World War I, aged 77, died in March

**Jerome Harvy Hunter**, Chicago, Meharry Medical College, Nashville, Tenn, 1921, aged 53, died, March 21, of pneumococcal meningitis

**Edward Ellsworth Campbell**, Douglas, Ariz, Chicago Homeopathic Medical College, 1890, aged 80, died, March 24, of chronic myocarditis

**Daniel Gott Hastings** Ⓢ Rochester, N Y, Harvard Medical School, Boston, 1888, aged 80, died, March 21, of arteriosclerosis and nephritis

**Ezra Wainford Longnecker**, Dayton, Ohio, Medical College of Ohio, Cincinnati, 1884, aged 82, died, March 5, of cerebral hemorrhage

**Alexander Anderson Sutherland**, Blubber Bay, B C, Canada, Trinity Medical College, Toronto, Ont, 1891, aged 76, died in January

**Wiley Clayton Nedrow** Ⓢ Friendsville, Md, University of Louisville (Ky) Medical Department, 1907, aged 58, died, March 9, of uremia

**John K Suckow**, Los Angeles, University of Southern California College of Medicine, Los Angeles, 1905, aged 69, died, February 3

**James A Miller**, Garrettsville, Ohio, Homeopathic Hospital College, Cleveland, 1886, aged 82, died, March 8, in Phoenix, Ariz

**Charles Ignatius Anders** Ⓢ Old Fort, Ohio, University of Wooster Medical Department, Cleveland, 1894, aged 72, died, March 8

**Rasselas Wagner**, Los Angeles, Missouri Medical College, St Louis, 1879, aged 86, died, February 18, of acute parotitis (nonepidemic)

**Arthur Lee Chapman**, Courtland, Miss (licensed in Mississippi in 1890), aged 64, died, February 14, of carcinoma of the bladder

**Samuel Michael Clurman**, New York, University and Bellevue Hospital Medical College, New York, 1900, aged 74, died in March

**George Monroe Cobb**, Ector, Texas, University of Tennessee Medical Department, Nashville, Tenn, 1895, aged 73, died in March

**Daniel H Crawford**, Charleston, W Va, Hahnemann Medical College and Hospital, Chicago, 1890, aged 76, died February 28

**William Marion Lauffer**, North Irwin, Pa, Western Pennsylvania Medical College, Pittsburgh, 1891, aged 78, died, February 24

**John P Hornig**, Cedarburg, Wis, Wisconsin College of Physicians and Surgeons, Milwaukee, 1901, aged 76, died, February 28

**Walter Carlton Bidelsbach** Ⓢ Waco, Texas, University of Texas School of Medicine, Galveston, 1918, aged 49, died, February 15

**Irving Edwin Brainard**, Wallingford, Conn, Yale University School of Medicine, New Haven, 1902, aged 64, died, February 13

**Ralph Motheral**, Hanford, Calif, Vanderbilt University School of Medicine, Nashville, Tenn, 1903, aged 64, died, February 13

**Henry Jefferson O'Brien**, Los Angeles, Medical Department of Hamline University, Minneapolis, 1895, aged 72, died, January 28

**Joseph Henry Mowers**, Shippensburg, Pa, University of Maryland School of Medicine, Baltimore, 1878, aged 87, died, February 7

**Edgar E Hodges**, Little Rock, Ark, University of Arkansas School of Medicine, Little Rock, 1906, aged 62, died, February 7

**Frank Eubank Booker**, Halifax, Va, Medical College of Virginia, Richmond, 1898, aged 67, died in March of cerebral hemorrhage

**Frederick Ackerman**, New York, University and Bellevue Hospital Medical College, New York, 1904, aged 62, died, March 18

**Joseph Ray Anderson**, Louisville, Ky, University of Louisville (Ky) Medical Department, 1893, aged 71, died, March 26

**Ignatius Michael Jarzynski**, Cleveland, Western Reserve University School of Medicine, Cleveland, 1914, aged 54, died, March 11

**Frank Barnard Sutliff**, Sacramento Calif, Albany (N Y) Medical College, 1878, aged 89, died, February 11, of coronary occlusion

**John Lorin Aird** Ⓢ Manhattan Beach, Calif, University of Colorado School of Medicine, Denver, 1926, aged 42, died, March 9

**Edward Atkinson** Ⓢ Niantic, Conn, University of Vermont College of Medicine, Burlington, 1893, aged 80, died, March 5

**Peter Beemer Davenport** Ⓢ Colesville, N J, New York University Medical College, New York, 1897, aged 72, died, March 8

**Chester Eugene Blackman**, Bridgeport, Conn, Long Island College Hospital, Brooklyn, 1897, aged 69, died, February 16

**John Robert Irwin**, Cobourg, Ont, Canada, University of Toronto Faculty of Medicine, 1902, aged 63, died January 12

**Joseph Harrison Riley**, Lexington, Ky, Louisville Medical College, 1898, aged 68, died, February 22, of cerebral hemorrhage

**Thomas E Shepard**, Tulsa, Okla (licensed in Oklahoma under the Act of 1908), aged 73, died, March 9, of pneumonia

**Howard Kenneth Shrom** Ⓢ Detroit, Jefferson Medical College of Philadelphia, 1924, aged 41, died in March

**Robert Bonney** Ⓢ Boston, Harvard Medical School, Boston, 1898, aged 83, died, March 22, at the City Hospital

## Bureau of Investigation

### SOME MISCELLANEOUS MEDICAL FRAUDS

#### A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

**Crampton's Products Inc.**—A James W. Crampton of Buffalo used this trade style in selling a mail-order pile cure known as Crampton's Pile Lene Suppositories. This seems to be the person who as James E. Crampton had originally conducted a similar business in connection with F. J. Lipinski, the two men trading as Grant Laboratories, Buffalo, and putting out something they called J. E. C.'s Rectal Remedy. As the result of a complaint that was filed against them by the Federal Trade Commission for representing their nostrum as a competent treatment for piles or hemorrhoids, these persons signed a stipulation with the Commission around July 1, 1937, in which they promised to discontinue the misrepresentations for their product and also to cease using the word "Laboratories" until they should actually be operating one. Whether Lipinski remained in the business is not clear, but the records do show that the name J. E. C.'s Rectal Remedy was changed to Crampton's Pile Lene Suppositories and marketed under the trade style Crampton's Products Inc. of Buffalo. The next government agency to take action was the Post Office Department, which objected to the representations that Pile Lene would quickly cure and give total relief from hemorrhoids regardless of the severity or duration of the disorder on the ground that such claims were fraudulent. Crampton made a general denial of the charges but put in no appearance at the hearing held on Dec. 2, 1940, when he was to have been present to show cause why a fraud order should not be brought against him. At that hearing the government's witnesses were the Post Office inspector who had investigated the case as well as a qualified medical expert and a government chemist. The latter testified that the treatment consisted of suppositories each averaging 1.96 Gm. in weight and containing 0.48 gram of the alkaloids of celandine and mullein in a tallow base. One suppository was to be taken at night and another the next morning until at least two weeks after all signs of hemorrhoids had disappeared. The medical witness testified that although these suppositories might produce a mild analgesic effect due to the depressant action of the ingredients on the nerve endings and mucous membranes with which they came in contact, the correct treatment of hemorrhoids was one based on the causative factors and a proctoscopic examination of the patient. He further stated that mild cases might be treated palliatively by the use of any lubricating substance to produce temporary relief but that to obtain complete relief or cure and prevent recurrence surgical procedures or the injection of sclerosing substances would be necessary. Accordingly the Post Office declared the Crampton scheme to be a swindle and debarred it from the mails by means of a fraud order issued Dec. 21, 1940, against Crampton's Products Inc. and their officers and agents.

**Regina's Herbatorium.**—From New York the concern that did business under this name promoted Lapidar through the mails by representations which the Post Office considered false and fraudulent. Among these were that the nostrum would dissolve and remove gall kidney and bladder stones, relieve and overcome epilepsy, prevent apoplexy, restore full and normal use of limbs to all persons who have suffered apoplectic attacks and prevent or overcome dizziness, cold feet, stiff limbs, faulty circulation, arteriosclerosis, carbuncles, skin diseases, blindness, baldness and swelling of the glands or limbs and do "some other things." It was shown also that the promoters sent inquirers circular matter describing not only Lapidar but several hundred other products which the same concern sold. Accordingly the Post Office ordered Regina's Herbatorium to show cause on Aug. 11, 1941, why it should not be the subject of a fraud order. The concern replied that it had forwarded the memorandum of charges and letter of citation to the Lapidar Company at Chino, Calif., which supplied it with Lapidar and the accompanying literature in the hope that the Lapidar Company would revise the objectionable advertising claims. The Post Office replied that as Regina's Herbatorium solicited remittances under its own name any fraud order issued would cover that name even if the Regina concern did not prepare its literature. Then came a letter to the Post Office from one C. P. Von Herzen of Los Angeles who stated that he was the attorney for Robert Mauer, owner of the Lapidar Company. He attempted to justify the literature and urged that no fraud order be issued with respect to the Lapidar product. No one representing Regina's Herbatorium appeared at the hearing of this case. There it developed that statements on the labels supplemented by chemical analysis and microscopical examination made by the Food and Drug Administration showed that Lapidar consisted of tablets weighing 1.4 grains each and containing licorice oil of anise, tansy herb, cascara bark, mumi, mullein, rhamnus, parietaria, dictamnus, sceselin, la erpitum, pumipinella, ononis, echinops, potentilla aurea, galicobdolon, tanacetum, scolopendrium, herniaria and other roots and barks. The chemist also testified that in seventeen of the tablets he found a trace of alkaloid. The directions were to take 5 to 10 tablets four times a day on an empty stomach. An expert medical witness for the government testified that this mixture had no therapeutic value beyond that of a laxative and would not overcome or cure the conditions for which it was sold. Hence it was held to constitute a swindle on the public and on Nov. 25, 1941, a fraud order was issued against the name Regina's Herbatorium debarring it from further use of the mails.

**The Champlon Institute.**—Under this title a Mrs. M. H. Champlon of Los Angeles was engaged in the mail order sale of a course of what she called simple scientific exercises for various eyesight defects. The Post Office implied that she might be the Mrs. Maud Champlon listed in the Los Angeles city and telephone directories as an astrologist. The treatment that Mrs. Champlon promoted was based on the preposterous theory that eye exercises cure far sightedness, myopia, old age eyes and astigmatism, restore normal vision and 'perfect sight' to persons afflicted with the eye defects mentioned and others without the necessity for wearing glasses. In fact some of the advertising stated: "The Champlon system is based upon the principles set forth by the Famous Dr. W. H. Bates in his book for doctors, 'The Cure of Imperfect Sight by Treatment without Glasses.' (Readers of THE JOURNAL are of course familiar with the Bates buncombe which was dealt with at some length in the issue of Oct. 13, 1923, page 1301.) For a mere \$3—which Mrs. Champlon pointed out was far less than the cost of properly fitted glasses—one could obtain the lessons and exercise chart with the assurance that you will always be able to look back to this as a red letter day in your life this day when you took the first step toward regaining normal vision. The scientific testimony presented by a government witness at the hearing of this case showed that exercises of the type prescribed by Mrs. Champlon are not new but that on the contrary their effects, limitations and possible benefits are well defined, that some exercises have a proper place when after careful examination and diagnosis of the patient's eyes there is found an imbalance of the extraocular muscles which may be benefited by certain selective exercises. The witness further testified, however, that the Champlon lessons evidently are based on the false theory that all defects of vision are due to imbalance or impairment of the extraocular muscles. It was shown that attempts by persons having hyperopia, myopia, presbyopia, astigmatism or combinations of these disorders to discard their glasses and employ the Champlon treatment might bring about unnecessary eyestrain, headaches, inflammation or other undesirable symptoms. As a result the Post Office declared that the misrepresentations made for the Champlon Eye Athletics System for Developing Perfect Eye Sight constituted a fraud and on April 4, 1941, the Champlon Institute and its officers and agents were debarred from further use of the mails.

**The Great Christopher Corporation and the Alright Specialty Company Ltd.**—According to the Post Office Department one Emil H. Funk started the first named concern in Buffalo and later added his wife and his son-in-law, Leo G. Dale, to his staff. Among the nostrums they put out were King's Ointment, Christo Hair Dressing (or Scalpolene) and Alright Shampoo-Shaving Cream (or Reliable Shampoo-Shaving Cream). Because of unwarranted claims made for these products Funk was cited by the Post Office in January, 1938, to show cause why a fraud order should not be issued against his business. Funk and Dale for their own protection then executed and filed with the Post Office an affidavit in which they agreed to discontinue the use of the mails in the sale of their preparations. It was learned, however, that Funk and Dale continued to answer inquiries regarding their hair growing treatment from Buffalo but directed inquirers in this country to send their orders to Stevensville, Ontario, Canada, where they were filled by a person whom they employed for that purpose and who appears to have operated as the Alright Specialty Company. Since these facts were evidence that Funk and Dale had not abided by the terms of their affidavit filed in March, 1938, but had continued the sale of the products through the mails, the Post Office on Sept. 17, 1941, ordered Funk to show cause on October 15, why a fraud order should not be issued against him and the two firm names that he used. After a postponement to October 27, Funk's attorney notified the Post Office that his client would not put up a defense but would consent to the issuance of a fraud order against him. At the hearing on October 27, the government produced an expert medical witness and also a chemist who had analyzed some of Funk's products. The latter reported the following composition:—King's Ointment, zinc oxide, 18.66 per cent; sulfur, 9.6 per cent; phenol, 2.45 per cent; volatile oils, 0.82 per cent; and traces of boric acid and camphor in an ointment base. Christo Hair Dressing, essentially sulfur, 5.5 per cent; salicylic acid, 0.68 per cent; resorcin, 0.60 per cent; and crude oil in a base of perfumed petrolatum. Alright Shampoo-Shaving Cream, white perfumed cream soap. King's Ointment was represented as a cure for leg sores, eczema and rectal irritation. Christo Hair Dressing and Alright Shampoo-Shaving Cream were claimed to produce a new crop of hair on shiny bald heads when used as directed. There was also mention of three additional nostrums which the government chemist apparently did not analyze: Kimo Tablets (to supply iron to the system), Asthma Remedy and something named more specifically, Indian Remedy for Asthma. In addition Funk sold formulas for preparations supposed to remedy heart disease, portitis, stomach disorders, lost manhood, gonorrhea and catarrh. The government's expert medical witness in this case pointed out the dangers involved in attempting to treat oneself for a good many of these conditions and also the worthlessness of patent medicines in such treatment. On Dec. 8, 1941, the Post Office issued a fraud order against the Great Christopher Corporation of Buffalo and its officers and agents, including E. H. Funk, President, and E. H. Funk, Manager, and the Alright Specialty Company Ltd. and its officers and agents of Stevensville, Ontario, Canada. In this connection it is interesting to note that Funk, at least for a time, did business under still another name, The Reliable Specialty Corporation, Buffalo, and that on Aug. 13, 1938, the Federal Trade Commission, after several hearings, ordered this concern to cease and desist from misleading and exaggerated representations in connection with the sale of certain patent medicines. The ones named in the order were Dr. King's Ointment, Scalpolene, Reliable Herb Tablet, Beat Sall Iron Compound Tonic Tablets, Reliable Anti-Stout Tablet, Reliable Cold Tablet, Rosola Anti-cup Powder, Reliable Herb Tea, Egyptian Asthma Remedy, Reliable Rheumatic Remedy and Great Christopher Corn and Callus Remedy.

## Correspondence

### CONTAGIOUSNESS OF ACUTE ANTERIOR POLIOMYELITIS

Contagiousness through direct personal contact in epidemic and nonepidemic periods of acute anterior poliomyelitis is regarded by many departments of public health as a settled fact. The quarantine laws, however, as to the length of isolation applicable to contacts of this disease vary in states, counties and cities. The student of epidemiology is frankly at a loss in interpreting quarantine laws except from a legal point of view, and perhaps all such laws should be remodeled in order to meet modern epidemiologic methods and knowledge. The degree of contagiousness or, better termed, the infectivity rate, as determined by secondary cases, which can be attributed to contact, varies in epidemic and nonepidemic periods of acute anterior poliomyelitis. Moreover, the epidemiologic and clinical evidence appears definite and almost conclusive that the infectivity rate due to contact is far less in acute anterior poliomyelitis than in any other communicable disease. Perhaps the fact that the inciting agent is a filtrable virus possessing no unusual degree of viability, and whose entry into the body is generally considered the nasopharynx, may be the determining factor in the limited contagiousness due to direct personal contact. The health official in times of elevated epidemic indexes is confronted with the closing of schools or delaying of the opening and the closing of swimming pools, theaters, churches and the like to children of susceptible age.

The beneficial effects of any one of these allegedly important quarantine or preventive measures, even when they are put into operation in their entirety, appear to be decidedly controversial. Therefore the conclusion of Casey (Observations of an Epidemic of Poliomyelitis, *Science* 95:359 [April 3] 1942) in describing a recent epidemic of poliomyelitis that "human travel was a major factor in the spread of the disease from neighborhood to neighborhood" deserves attention from health officials. Furthermore, the additional conclusion that "eighty per cent of the poliomyelitis patients had probably visited or been visited by a prior poliomyelitis patient" is one of observation only and not especially corroborative.

In the 1934 outbreak of this disease in San Francisco (Geiger, J. C., Becker, G. H., and Gray, J. P. Acute Anterior Poliomyelitis, *THE JOURNAL*, Aug. 4, 1934, p. 342; Geiger, J. C. Acute Anterior Poliomyelitis. The Possibility of the Spread as a Result of Direct Personal Contact—A Study of 385 Contacts, *California & West Med* 48:245 [April] 1938) 181 close personal contacts of 68 proved cases were carefully studied. The 181 contacts were followed for at least six weeks by epidemiologists and the public health nurse. The disease developed in only 2 of the contacts. Ten of the remaining contacts showed at various periods of the time elevations of temperature, sore throat, muscular pains and malaise, but careful clinical observation and laboratory examination eliminated all as having clinical acute anterior poliomyelitis.

Despite the findings of Casey, the epidemiologist must seek a more definite answer as to the modes of spread of this disease or accept the evidence that the population immunity is not an inconsiderable factor, since acute anterior poliomyelitis affects very few persons in a community in comparison with other communicable diseases. It is unfortunate that departments of public health usually possess meager or no information as to the source or route of infection in cases reported, especially in epidemic periods.

J. C. GEIGER, M.D., San Francisco

### VENOGRAPHIC DIAGNOSIS OF THROMBOPHLEBITIS OF THE LOWER EXTREMITIES

*To the Editor*—In the April 4 issue of *THE JOURNAL* appeared an article entitled "The Venographic Diagnosis of Thrombophlebitis of the Lower Extremities" by Dr. Arnold Starr and his associates. The authors describe a method of visualizing the deep venous system of the lower extremities as an aid in the diagnosis of thrombophlebitis. The technic that they use involves the injection of diodrast into a deep vein behind the external malleolus, which is found after making a small incision. This method is that of G. Bauer, who described it for the first time in the *Acta chirurgica Scandinavica*, published in 1940.

The studies made by Starr and his associates are interesting and significant, but I should like to call attention to a somewhat similar method of visualizing deep venous thrombosis which I published in 1939. This article entitled "Unilateral Enlargement of the Lower Extremities Accompanying Varicose Veins, with Roentgen Studies of 'Deep Venous Block,'" was published by the *American Journal of Roentgenology and Radium Therapy*. It described a simplified method of visualizing the deep venous system by the injection of the same reagent, diodrast. The difference between the two methods is simply in the choice of the vein for the injection.

The method that I described consisted of injection into any superficial vessel, while Starr cuts down on a deep vein for his injection. It is true that with my method the normal deep venous tree is not visualized, but in cases of block the deep vessels show up beautifully with this simple technic. It is also true that when no superficial vein can be found the more involved technic of Bauer and Starr is of value. The point I wish to make, however, is that a prior technic which has been adequately described in the literature should in my opinion be mentioned in an article which merely refines an already existing method of treatment.

H. I. BIEGELEISEN, M.D., New York

### USE OF SULFONAMIDE SOLUTIONS IN THE NOSE

*To the Editor*—I read in *THE JOURNAL*, March 21, a communication from Dr. Walter D. Klestadt and a reply to this communication by Dr. Russell Fletcher concerning the use of sulfonamide solutions in the nose, and in view of the fact that there is some controversial discussion I should like to add something from my experience on the use of a solution of sodium sulfathiazole in the nose.

After publication of Dr. F. M. Turnbull's article last year I began using a 5 per cent solution of sodium sulfathiazole by means of nasal tamponage. These packs were inserted, for the most part, in the middle meatuses following the application of 5 per cent cocaine and were left in place from fifteen to thirty minutes. The frequency of treatment varied with different patients, sometimes daily, sometimes several days apart.

I have used this solution on more than 300 patients, and I have had more than seventy-five applications over a period of six months. These patients were observed closely and at no time have I detected any sloughing of the nasal mucosa. True, there were some patients who did not tolerate the drug as was manifested by reactions resembling an allergic rhinitis following its use. For the most part, patients were impressed with the fact that there was very little reaction following treatment. There was less turgescence of the nasal mucosa hours later than they had experienced from other treatments.

We found that when the solution had been made up a few days it became quite irritating, as evidenced by much turgescence a few minutes after application. This

also corroborated by patients who were given solutions to use in the prescribed atomizers at home. One woman, in particular, had considerable nasal discomfort when she went back to using the spray after having had it for a previous cold about a month before.

I found the solution effective in certain types of sinusitis, namely those cases in which there is considerable thick, purulent secretion with a tendency to stickiness and crusting of the nasal mucosa. I have also used it in the Proetz displacement treatment but did not observe that it had any particular value used in this way over tamponage. Its use in cases of acute rhinitis, namely the so called acute cold, were in general quite disappointing. It seemed to offer no short cut or quick relief for the symptoms of this well known malady.

My main object in writing this letter, however, was to say that if the use of sodium sulfathiazole in the nose has produced sloughing, I have failed to observe it.

FORREST W. MFRICA, M.D., Lakewood, Ohio

### RESUSCITATION IN ASPHYXIA

*To the Editor*—I noted with interest the article entitled "Resuscitation in Advanced Asphyxia" by Drs. George L. Birnbaum and Samuel A. Thompson and Mr. Eugene Ostrow which appeared in *THE JOURNAL* on April 18. I approached this with an open mind and with the hope that I might find new information. However, having read the text carefully, I feel obliged to challenge its subject matter and what would appear to be its implications.

As to the subject matter, I refer the reader to page 1364 line 7, either a specially fitted face mask and pharyngeal airway or a special tracheal catheter with rubber inflation cuff to prevent leakage. This casual reference to the basic approach to the technic advocated is not scientific. Any one at all familiar with the mechanical operation of a suck and blow apparatus is fully aware that it can operate only in an airway of guaranteed patency. Therefore, just what was the preparation of the airway in the experiments referred to and on which findings was the relative value of each technic measured?

Such an approach certainly does not serve to clarify a problem which the authors find confused. If the authors intend to go into subsequent detail, it would seem out of order to present the body of their observations and conclusions without prefacing them with the technical approach, which if placed at the end of the matter is not likely to be read.

Page 1367 line 17. When respiration has been restored and acts out of step with a mechanical resuscitator, it indicates the successful return of spontaneous respiration and it is time to desist from the use of mechanical resuscitation.

Theory and practice agree that to employ a practice known to be dangerous (inhibiting spontaneous rate and rhythm) in this case a matter of life and death and not merely a question of esthetic rhythm is meddlesome to say the least. Furthermore if this spontaneous respiration is inhibited, how can it warn the operator to desist?

Finally is it possible that the authors have missed the point of the need of muscle tone in artificial respiration? This, of course has to do only with the recoil of the chest in the prone pressure technic following compression. It has nothing to do with spontaneous expiration following insufflation. In this instance a person at rest can be as flaccid as a collapsed toy balloon. The chest empties itself because it has been stretched not because it possesses muscle tone. A thawed cadaver two weeks old will demonstrate a perfectly good expiration following insufflation. Suction is not needed to accomplish this.

The implications of this presentation should it be felt, have been tempered by a clear reference differentiating the laboratory

dog from the clinical patient. In ordinary laboratory reports this differentiation is apparent and confusion does not occur. In this presentation, however, there seems to be no hesitation in passing from the laboratory to the clinic and back again, implying the same values in the two. The implication read into this presentation by the average reader may be expected to be somewhat as follows: "Here is an article, a scientific article, from a research laboratory which keeps on repeating that the suck and blow technic, by a named apparatus, is the best technic, and here are figures to prove it. All we have to do is to get ourselves a suck and blow apparatus and our asphyxial problems will be at an end."

If there is confusion in the field of asphyxia, it is due to just this sort of gratuitous overlapping of laboratory and clinic without regard for the theoretical and practical gulf which separates the two. Because of the ease with which an exact knowledge and the correct treatment of the needs of a particular case may be avoided, by placing all responsibility on a mechanical robot, the prevention of asphyxial death is now and threatens to remain on the low level of commercial competition. Resuscitation apparatus should be regarded as a means to an end—the simpler it is, the safer it is. The care of the asphyxiated has not followed the classic formula "Follow the physiologic indications." Until it does, confusion will continue.

PALUEL J. FLAGG, M.D., New York

### TOXIC EFFECTS OF FUADIN AND ANTIMONY AND POTASSIUM TARTRATE

*To the Editor*—In the *South African Medical Journal* Nov. 8, 1941, page 440, E. Ross Marshall of New York is reported to have said, in comparing antimony and potassium tartrate with fuadin (*J Nat Med* 33:105 [May] 1941) that fuadin is the better drug since it is less toxic. As it is much less toxic, almost no untoward symptoms are noted from its use. Similar statements have been made in regard to the use of antimony in the treatment of leprosy.

No thoughtful reader can think that a 6 per cent solution is as 'toxic' as a powder containing from 36 to 39 per cent of the same drug, and an equivalent amount of the two solutions reveals that the solution of antimony and potassium tartrate is free of the undesirable effects of the pyrocatechol compounds.

Estimates of cure are difficult in instances in which extensive parasitic diseases may account for a raised eosinophil count and in infections with *Schistosomum mansoni* whose escaping ova are few especially in cases of old infection or when most of the worms are males but evidence is still needed to show that less than 0.5 Gm of antimony will effect a permanent eradication of all the schistosomes from an infected person and there is a widespread danger of resting content with the disappearance of symptoms which may easily be procured by any antimony compounds.

F. GORDON CRAWSTON, M.D. (CANTAB),  
Durban Natal South Africa

### SIR D'ARCY POWER

*To the Editor*—With the approval of his son Air Commodore Power I am collecting material for a life of the late Sir D'Arcy Power. I shall be grateful if any of your readers who possess letters from Sir D'Arcy or other relevant material will be kind enough to send me copies. Originals lent would be copied and immediately returned.

W. R. LEFANEL,  
Lincoln's Inn Fields,  
London W.C.2

NATIONAL BOARD OF MEDICAL EXAMINERS *Parts I and II* Various centers, June 22-24 *Part III* Various centers, June or July Exec Sec, Mr Everett S Elwood, 225 S 15th St, Philadelphia

##### EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY *Oral Part II* Atlantic City, June 6-7 Sec, Dr Paul M Wood, 745 Fifth Ave, New York

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY *Oral Groups A and B* Cleveland, Jan 14-15, 1943 Final date for filing application is Dec 7 *Written* Various centers, Nov 16 Final date for filing application is Oct 5 Sec, Dr C Guy Lane, 416 Marlboro St, Boston

AMERICAN BOARD OF INTERNAL MEDICINE *Written* Oct 19 Final date for filing application is Sept 1 Sec, Dr William S Middleton, 1301 University Ave, Madison, Wis

AMERICAN BOARD OF NEUROLOGICAL SURGERY *Oral* New York, May 12-13 Sec, Dr R Glen Spurling, 404 Brown Bldg Louisville, Ky

AMERICAN BOARD OF OPHTHALMOLOGY *Oral* Baltimore June 6 and Philadelphia, June 8 Sec, Dr John Green, 6830 Waterman Ave, St Louis

AMERICAN BOARD OF ORTHOPAEDIC SURGERY *Oral and Written* Chicago Jan 9-10 Final date for filing application is Nov 1 Sec, Dr Guy A Caldwell, 3503 Prytanis St, New Orleans

AMERICAN BOARD OF PATHOLOGY *Oral and Written* Richmond Va, Nov 9-10 Final date for filing application is Sept 1 Sec, F W Hartman, Henry Ford Hospital, Detroit

AMERICAN BOARD OF PEDIATRICS *Written* Locally, Sept 18 *Oral* Chicago Nov 2-3 Final date for filing application is July 1 Sec, Dr C A Aldrich, 707 Fullerton Ave Chicago

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York, December Final date for filing application is Oct 1 Sec, Dr Walter Freeman, 1028 Connecticut Ave N W, Washington, D C

AMERICAN BOARD OF UROLOGY If a sufficient number of applications are received an examination will be held in the east at the same time or shortly after one of the national meetings Sec, Dr Gilbert J Thomas 1409 Willow St, Minneapolis

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Right of Sanipractor or Optometrist to Render the Care to Be Provided Indigent Senior Citizens at State Expense**—An initiative measure (No 141) adopted by the electorate of Washington in November 1940 provides senior citizen grants, that is, stated monthly cash payments to indigent senior citizens of the state Section 15 of the measure provides

In addition to Senior Citizen Grants, the department (Social Security) shall provide for those eligible medical, dental, surgical, optical, hospital and nursing care by a doctor of recipient's own choosing,

One Martin, an eligible senior citizen, requested authorization from the local agency charged with the administration of the law for treatment by a certain licensed sanipractor, a practitioner of a method of drugless healing legalized within restricted limits by state law His application was denied and, in accordance with the provisions of the law, he appealed to the department of social security, state of Washington, which likewise refused his application The superior court, Thurston County, however, reversed the order of the department and, in effect, ordered the department to authorize the treatment of Martin by the sanipractor, and the department appealed to the Supreme Court of Washington

The question here for decision, said the Supreme Court, is the meaning to be given the word "doctor" as used in the section of the law quoted The department contends that, by the use of that term, it was the intention to allow the recipient to have only such treatment as could be administered by a regularly licensed medical practitioner On the other hand, Martin contends that it was the intention to give the recipient the right to choose any one authorized to give treatment, such as drugless healing, within the scope of the license which had been issued

to such practitioner If, continued the court, the contention of the department should be sustained, then the words in the statute "hospital and nursing care" would have so meaning This is made obvious by assuming that the act had used only those words and that it had read as follows "Additional Care In addition to Senior Citizen Grants, the department shall provide for those eligible hospital and nursing care by a doctor of recipient's own choosing" A statute should not be given an interpretation which would make it an absurdity when it is susceptible of a reasonable interpretation which would carry out the manifest intent of the legislature Further, a statute should be so construed that, if it can be prevented, no clause, sentence or word shall be superfluous, void or insignificant The drafters of the law here in question and the people who voted for the measure undoubtedly intended that every word used in section 15 should have some meaning It was intended, by the use of the word "doctor," to include any person who was authorized to practice any of the healing arts specified, so long as such practitioner did not exceed the scope of his license or certificate

The Supreme Court, accordingly, in effect, ordered the department to authorize treatment by the sanipractor at the expense of the state

In a similar decision handed down the same day in *O'Neil v Department of Social Security*, the Supreme Court also ordered the department, for the reasons stated in the Martin decision, to authorize optical care to be rendered another senior citizen by a licensed optometrist—*Martin v Department of Social Security*, 121 P (2d) 394, *O'Neil v Department of Social Security*, 121 P (2d) 396 (Wash, 1942)

**Malpractice Failure to Instill Silver Nitrate Prophylactic into Eyes of Newborn Baby**—The plaintiff, an infant 1 year of age, by his next friend, instituted a malpractice action against the physician defendant for loss of his eyesight due to "gonococci infection," allegedly caused by the failure of the physician, who attended at his birth, to instill a silver nitrate prophylactic in his eyes At the conclusion of the evidence a motion by the physician for a peremptory instruction in his favor was overruled and the jury returned a verdict in favor of the plaintiff From a judgment on the verdict, the physician appealed to the Court of Appeals of Kentucky

The motion of the physician for a peremptory instruction in his favor was based essentially on two contentions, namely (1) that negligence on his part had not been established and (2) that the evidence did not show that the negligence, if any, was the proximate cause of the injuries suffered by the plaintiff The court believed, however, that the evidence conclusively established negligence on the part of the physician The physician admitted that he did not place silver nitrate or any other prophylactic in the eyes of the plaintiff either at birth or any time thereafter It appeared that the plaintiff was born about 5 o'clock in the morning and that when the physician attended the birth he had an old bottle of nitrate of silver which had crystallized, and the physician was "afraid to use it" He discussed the matter with the mother and told her that because of the hour the drug store was not open and it had never been infected with gonorrhea it was not imperative to use silver nitrate but that if she had ever had the disease he would write a prescription, which could be filled at the drug store when it opened and be used in the eyes of the child He returned later in the day to visit the mother but did not bring any silver nitrate with him Physicians called by the plaintiff testified that it is the recognized practice of the medical profession in communities and neighborhoods similar to that involved in this case to drop silver nitrate in the eyes of a child immediately after delivery A physician, said the court, liable for an injury to his patient resulting from want of required care and skill or from omission to use reasonable care and diligence in his treatment of the patient The standard of knowledge, skill and required care which physicians must possess and exercise is such reasonable and ordinary knowledge, skill and diligence as physicians in similar neighborhoods and surroundings ordinarily use under like circumstances The evidence that the physician failed to place a prophylactic in the eyes of the newborn child is sufficient conclusion to establish negligence on his part in the light of the law

dicted medical testimony that in all localities physicians ordinarily use silver nitrate or some other prophylactic in the eyes of a child at birth and that reasonable care and diligence require such to be done.

As to the second contention involved in the physician's motion for a peremptory instruction in his favor, namely that the evidence did not show that the negligence of the physician, if any, was the proximate cause of the injuries, the court likewise thought that the evidence as to causation was sufficient to submit that issue to the jury. It appeared that the father of the plaintiff had become infected with gonorrhea some two years before the birth of the plaintiff, and while a microscopic examination made of a smear taken from the mother about ten days after the child's birth was reported to have been negative, the evidence was such as to indicate that the child had become infected from the mother at birth. There was evidence that forty-eight hours after birth the plaintiff's eyes became irritated, that twenty-four hours later they became very red and that on the fourth day after birth pus appeared in both eyes. Ten days after birth the child was pronounced totally blind from gonococcal infection. The physician made some attempt by the evidence he introduced to imply that the gonococcal infection in the child may have been due to handling after birth by the father or by a maid, who at the time seemed to have been infected with a chronic case of gonorrhea. The evidence seemed to indicate, however, that neither the father nor the maid touched the child until after the infection had set in. Further evidence, said the court, as to the existence of the infection at the time of birth is the fact that both eyes of the infant were infected. That condition in reason would be more apt to exist if the infection were obtained from the mother at birth than if it were contracted after birth from an outside agency. If the infection had appeared in but one eye, such fact would have inclined the mind to the opinion that the infection had come from an outside source. The fact that there is evidence that the infection could have come from the maid or from the father after the child was born merely raises an issue of fact for the determination of the jury, whose decision, once made, becomes final and binding on the appellate court. The court accordingly concluded that the trial court properly submitted the case to the jury.

However in view of a remark made by the counsel for the plaintiff, which indicated that counsel for the defendant represented an insurance company, the Court of Appeals found it necessary to reverse the judgment and remand the case for a new trial.—*Walden v. Jones*, 158 S. W. (2d) 609 (Ky., 1942).

**Malpractice Alleged Failure Timely to Aspirate Infected Hip Joint**—The plaintiff, on Feb. 18, 1936 entered a small hospital operated by the physician defendant for treatment of pneumonia and was discharged as convalescent on March 7. Shortly after discharge he complained to the physician of aching joints and medication was prescribed. Thereafter the patient's 'trouble localized or settled in his left hip.' On April 23, after a thorough physical examination, the physician made a tentative diagnosis of 'acute infection, arthritis of left hip precipitated by trauma.' Roentgenograms of the hip made at that time showed 'normal bone texture, no evidence of periosteal thickening and no sign of cartilage destruction.' Two days later, on the physician's suggestion the patient again entered the hospital. He was put to bed and a Buck's extension was applied to the leg. Treatment that was given the patient between that date and May 29 consisted of the extension of the limb for about two weeks, constant heat, Oxorte B tablets, and other medication to induce sleep or relieve pain. Other roentgenograms were taken. During this time the patient complained constantly of severe pain. On May 29 the physician explored the hip joint with an aspirating needle and withdrew pus, which contained pneumococcus germs. That afternoon the physician made a posterior incision and established drainage. Thereafter the patient remained at the hospital under treatment until August 14, during which period drainage was maintained, the wound was dressed ultraviolet and infra-red rays were applied, the limb was again extended for a period, some irrigation was attempted and medicine was given to relieve pain. On August 14 the

patient was taken to a large clinic where by examination and roentgenograms it was discovered that the cartilage of the left hip had been destroyed. While in that clinic the sinus of infection was curetted, drainage maintained and a spica cast applied. The patient was discharged August 27 and thereafter visited the clinic in January, March and October 1937, during which visits different casts were applied. The drainage had not ceased until sometime before the last trip in October 1937. By that time the hip joint had fused and there was practically no motion in it, and as an end result the patient had a stiff hip and an impaired knee. Eventually the patient brought suit against the physician defendant for malpractice, asserting in substance that the physician defendant was negligent in that although he had determined that the patient was suffering from an infectious arthritis on April 23, 1936 he failed to aspirate the hip and establish drainage until May 29, 1936. At the close of the patient's evidence, the trial court directed a verdict in favor of the physician and the patient appealed to the Supreme Court of South Dakota.

Because, said the Supreme Court, the central issues of this case, namely negligence and its causal connection with the injury suffered by the patient turn on scientific questions that laymen are not qualified by learning or experience to answer, the patient was required to establish those elements by the testimony of expert witnesses. To establish these elements the patient called two physicians. One of these experts testified that a physician would want to be certain that there was pus before he aspirated or opened a hip joint. The other physician was careful to predicate his testimony on the assumption that the attending physician knew that he was dealing with a septic hip. In view of these facts said the court there is room for grave doubt as to the sufficiency of the evidence produced by the patient to warrant an inference of negligence on the part of the physician. However, it is unnecessary for us to determine that issue and we assume, but do not decide, that there is sufficient evidence in the record to support an inference of negligence in failing to establish drainage from the hip at an earlier stage of the treatment. Even so continued the court, the evidence must be sufficient to establish a causal connection between the assumed negligence of the physician and the lamentable resulting condition of the patient's hip. The standard of treatment established by the testimony of the physicians called to testify by the patient included drainage of the infected area as soon as the physician was certain of its septic condition. However, one of the experts addressing himself to the nature of the patient's malady, testified that 'there is little hope of preserving joint motion even with early drainage, and such an infection is very difficult to treat and very slow in healing.' Further, both of the physicians called by the patient treated the patient during the final period of his illness and gave direct testimony as to his condition. Speaking from personal knowledge of his case, they asserted that they discovered nothing in his condition which indicated neglect on the part of the defendant physician. In other words, both of these physicians viewed the patient's unfortunate condition as an expected result of the infection. The most that can be gathered from the evidence as bearing on the issue of causation is that early drainage and exact classification of the attacking organism improves the prognosis. Thus the record discloses that testimony of the physician witnesses called by the patient attributed the patient's ultimate condition to either of two possible causes, and only if the injury to the patient resulted from one of those causes—namely negligence on the part of the physician—would the physician be legally liable. As was said by the Supreme Court of Minnesota in *Jates v. Gamble* 198 Minn. 7, 268 N. W. 670.

In negligence cases and especially in malpractice cases proof of causal connection must be something more than consistent with the plaintiff's theory or how the claimed injury was caused. The burden is on plaintiff to show that it is more probable that the harm resulted from some negligence for which defendant was responsible than in consequence of something for which he was not responsible. An inference, continued the court that it is more probable that the patient's impairment resulted from the defendant's assumed negligence than from

the normal ravages of the infection is without substantial support in the expert testimony and is therefore without substantial support in the evidence. Such an inference would rest on speculation and conjecture and a verdict based thereon could not stand.

The Supreme Court accordingly concluded that the trial court had not erred in directing a verdict in favor of the physician—*Lohn v Watson*, 2 N IV (2d) 6 (S D, 1942)

**Malpractice Unjustifiable Detention of Patient in Hospital After Operation**—The plaintiff, in this action against the defendant physician, alleged that she entered the Claxton Hospital, a private hospital operated by the defendant for the purpose of undergoing an operation for the removal of a tumor by the defendant, that the operation was successful and that the plaintiff was advised that she would be able to leave the hospital in about twelve days. On the eleventh day, it was further alleged, the defendant forcibly administered an injection into her arm which "doped and dumfounded her faculties" and rendered her unable to move, and similar injections were made thereafter at intervals, necessitating a stay in the hospital for over four months. This was done by the defendant, it was alleged, in conspiracy with relatives of the plaintiff, one of whom was a physician, who desired to obtain control of the plaintiff's property. As a result, the plaintiff alleged that she was damaged to the extent of more than \$3,500. The defendant's demurrers to the petition were sustained by the trial court and the action was dismissed. The plaintiff then appealed to the court of appeals of Georgia, division No 2.

The defendant contended that the plaintiff's petition embodying the aforementioned allegations failed to state a cause of action. The court held that the defendant had a twofold duty toward the plaintiff, first as a physician employed to perform an operation and second as the operator of a private hospital in which the plaintiff became his patient. In his capacity as a physician, the defendant was required to exercise such reasonable degree of care and skill as was needed to accomplish the plaintiff's recovery. Instead of ministering to her in such a way as to facilitate her recovery of good health, it was alleged that she was forced by the defendant, through consultation and conspiracy with others, to submit to injections "of dope or other powerful drug," and that this rendered her incapable for several months of resisting the unlawful practices named. "Where a surgeon enters into an agreement with a person merely to perform a certain operation, and the surgeon, in violation of the contract, goes farther, without an emergency, and performs another operation which is unauthorized by the agreement, or by an emergency necessitating the additional operation, and injury results to the patient, the surgeon cannot relieve himself from liability by showing skill and care in the other operation." *Perry v Hodgson*, 168 Ga 678, 148 S E 659. The court of appeals admitted that it was sometimes necessary for a physician to administer a drug to a patient. The plaintiff alleged, however, that the injection was only for the purpose of frustrating her recovery rather than aiding it. Thus, even though the operation and the subsequent injection were each successfully and skillfully performed, the court of appeals concluded that if the allegations were true the defendant did not measure up to the degree of care and skill required of him on behalf of his patient. In his capacity as owner of the private hospital in which the plaintiff was a patient continued the court, the defendant was required to exercise such reasonable care in looking after and protecting the patient as the patient's condition required. If the defendant conspired with other persons to delay the plaintiff's departure from the hospital and administered drugs to the plaintiff in furtherance of that conspiracy, he failed to use such care as was necessary properly to supervise the plaintiff and adequately protect her interests. The court therefore concluded that the allegations of the plaintiff's complaint clearly charged the defendant with malpractice and that the trial court erred in sustaining the demurrers and in dismissing the action—*Lord v Claxton*, 8 S E (2d) 657 (Ga, 1940).

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamp to cover postage (6 cents if one and 18 cent if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

Halitosis in Relation to Oral Diagnosis B B Crohn New York—p 109

**Adenocarcinoma of Maxilla**—Thoma reports 5 cases of adenocarcinoma of the maxilla and discusses the invasive character of the tumor and its tendency to recur after operation and to extend into the paranasal sinuses. Osseous and visceral metastasis may occur. Therefore adenocarcinoma should receive prompt and radical treatment by a wide excision including the adjacent bone and followed by irradiation. Local recurrences are common and should be dealt with immediately or the prognosis will be poor.

**Sulfathiazole Therapy in Cellulitis**—Kayne employs the following treatment for early cellulitis. He applies cold compresses externally for fifteen minutes of every hour for the first twenty-four to forty-eight hours. Wet warm compresses externally when definite fluctuation is anticipated and when it is desirable to hasten pointing of the abscess, and irrigation with a hot 12 per cent solution of sodium sulfate. Magnesium sulfate sometimes causes patients to complain of nausea besides sodium sulfate is more hygroscopic. The treatment of cellulitis with definite abscess formation is early incision drainage and irrigation at home with a 50 per cent urea solution. A dressing saturated in urea should be applied and changed every day until the abscess is evacuated. Urea eliminates fetid odor and aids liquefaction. Prompt and energetic treatment with sulfanilamide is imperative for patients who have a persistent temperature of 102 F or more after incision and treatment with sulfathiazole for those who appear toxic and may have a secondary streptococcal or staphylococcal infection. Rest in bed is important. Patients given sulfathiazole should be under constant supervision. If a high temperature continues even though the infection is receding and the general condition is improving treatment with sulfathiazole should be withdrawn. Such reactions as nausea vomiting headache or dizziness are common but not alarming. If vomiting is severe the drug should be given in milk or rectally. The patient with advanced diffuse suppurative cellulitis with systemic complications especially if

bacteremia is present, should have the benefit of intravenous infusion of saline and dextrose solutions, sulfathiazole, blood transfusion and neocarsphenamine. Sulfathiazole and urea have proved beneficial adjuncts in the treatment of cellulitis of the face and neck.

**Capsular Polysaccharide in Blood of Patients with Pneumonia**—Bulantz and his associates determined the circulating capsular polysaccharide in the blood of 135 patients treated for pneumococcal pneumonia. In earlier studies it was observed that the presence of free polysaccharide, which is more rapidly detectable than bacteremia, makes the prognosis grave. To determine the presence of circulating capsular polysaccharide, 0.5 cc of a patient's serum is placed into each of three 10 by 75 mm pyrex tubes and 0.5 cc of the optimal dilution of homologous type specific rabbit antibody solution is added to the first tube, 0.5 cc of a heterologous rabbit antibody solution to the second tube and 0.5 cc of physiologic solution of sodium chloride to the third tube. Six additional positive and negative control tubes are prepared. All tubes are centrifuged at 2000 revolutions per minute for thirty minutes. When capsular polysaccharide is present in the serum a precipitate appears in the first tube but not in the second and third. The controls yield the expected results. Circulating capsular polysaccharide was present in the blood of 16 of the 135 patients, 11 had type III, 3 type VII and 2 type VIII pneumococcus pneumonia, an incidence of 17.9 per cent for the three types of pneumococcus. There were 16 deaths in the total series 10 among the 16 in whose serum capsular polysaccharide was present. Pneumococci of type III form large capsules and produce large quantities of capsular polysaccharide. The poorer response to serum therapy of infection (7 of the 11 patients died) caused by this pneumococcus as compared with the response of infection due to other types of pneumococci may be due to this characteristic. It is also possible that the carbohydrate of type III pneumococcus is less firmly bound to the organism than is the carbohydrate of other types of pneumococci. The increased fatality rate among the patients with a positive reaction for circulating capsular polysaccharide is not correlated with the number of lobes involved. It has been demonstrated that the growth inhibition and the pneumococidal action of sulapyridine in vitro is not affected by the addition of capsular polysaccharide. Accordingly the mechanism by which capsular polysaccharide increases the fatality rate must be sought in the effect of that substance on the immune mechanisms important to recovery. Capsular polysaccharide has been demonstrated to be specifically antiphagocytic and therefore specifically to inhibit phagocytosis to make avirulent pneumococci virulent and to augment the virulence of virulent organisms. The effectiveness of sulapyridine in pneumococcal infection results from its bacteriostatic action and from the immune substances which develop during the disease. An increase of capsular polysaccharide in the blood of the patient with pneumococcal pneumonia may be accom-

panied by "neutralization" of antibodies. Furthermore, Tunnicliffe suggested that the phagocytosis that sulfapyridine promotes in cultures of plain broth but not in cultures of dextrose broth may be related to an increased concentration of capsular polysaccharide in the cultures of dextrose broth, as compared with the concentration in those of plain broth. Specific antibody should be administered to patients in whom circulating capsular polysaccharide is detected so as to neutralize the anti-immune effects of the latter.

**Coccidioidal Arthritis**—Rosenberg and his co-workers report the third case of coccidioidal infection encountered at the Mayo Clinic. A man aged 25 came to the clinic with pain and swelling of both ankles of a year's duration. He had worked in the San Joaquin Valley for four years previous to the onset of his illness, when he had a dry cough, generalized aches, headache and increase of temperature up to 104 F. After three days of fever a generalized rash appeared on the face, trunk and extremities. A low grade fever persisted. Four months later a number of red, indurated lesions appeared on the dorsum of each hand and on the outer aspect of the left thigh. The lesions persisted for two or three weeks, were slightly painful and healed without leaving scars. A month later the patient returned to work, although he continued to have a low grade fever in the afternoon. Three days after his return to work swelling appeared about the left foot and ankle, with pain on weight bearing, and one week later the right foot and ankle swelled and became painful. In a year pain on weight bearing became intolerable and the patient had to stop working. Laboratory studies at the clinic did not reveal any striking abnormalities. His condition bore a resemblance to tuberculosis, but the history and the bilateral involvement were atypical. The posteromedial aspect of the right ankle was incised, and part of a sac filled with cheesy necrotic material was removed for examination. The wound healed by primary intention. Search with high magnification disclosed large, double contoured, refractile bodies containing minute, rounded, sporelike forms. A diagnosis of coccidioidal granuloma was made. The spore filled "capsules" contained the organism *Coccidioides immitis*. Sulfanilamide and roentgen irradiation over the ankles proved ineffective. At the time of the patient's dismissal from the clinic his condition seemed to be essentially unaltered.

**Edema with Unexplained Hypoproteinemia**—Rytand discusses the occurrence of edema with hypoproteinemia apparently due to defective protein formation in the serum in a young woman with no apparent loss or lack of protein and without a hepatic or renal disorder. Four similar cases have already been reported. The syndrome, an inexplicably defective formation of serum proteins, may be but an exaggerated expression of the varying abilities of different persons to form serum protein, while ordinarily loss of protein or nitrogen is required to unmask such differences, here the defect appears spontaneously. Although some plasma protein is formed in the liver, the bone marrow (or the reticuloendothelial system) may be another site

- Sequelae of Intraspinal Anesthesia. G D Stanley, Calgary, Alta—p 164

**Inefficacy of Sulfapyridine in Influenza**—Adamson and Flett observed that the sequence of events in patients with uncomplicated influenza treated and not treated with sulfapyridine is not dissimilar. Of 68 men from the active service forces with influenza, 42 were and 26 were not given sulfapyridine. The epidemic occurred during nine days. All the patients were given full bed care, and treatment was started on the first day in 6, on the second day in 30 and on the third day in 32. The pulse rate and the elevated temperature both had fallen to normal by the sixth day in the two groups of patients. However, since pneumonia due to secondary bacterial invasion is the chief complication in influenza, it is justifiable to prescribe prophylactic doses of sulfapyridine or sulfathiazole for all patients with influenza. 0.5 Gm three or four times a day will inhibit the growth of secondary invaders, and if this dose is given only to four days toxic effects will rarely occur.

**Septicemia**—McLellan and Goldbloom suggest that some of the recent improvement in the mortality rate from staphylococcal septicemia is the result of the more frequent diagnosis of mild cases. Depending on conditions there is likely to be a considerable variation in the percentage of deaths in different institutions. A possible individual prognostic basis, with rare exceptions applicable to the authors' cases, was that a patient who had a history of a recently healed staphylococcal infection or in whom the infection was well localized and the colony count on blood culture was low survived, while a patient with no such history or with a spreading infection and a high colony count died. The patient whose history of localization and colony count were contradictory fell in the intermediate group, either he survived or his death was delayed. The lives of patients who might otherwise have died were possibly saved by the intensive treatment of 1 with antitoxin and of the 6 with antitoxin and sulfathiazole. However, of 33 patients early treated 17 died and 16 survived, and therefore it is that the localization and healing of an infection are the two determining points for the prognosis. The experimental value of antitoxin, antibacterial serum and the sulfonamides is discussed, and it is suggested that these be considered in therapy in human disease.

**Excretion of Steroids and Cancer**—Pearlman analyzed the pooled urine of men with carcinoma of the intestine and of the bladder and the pooled urine of women with carcinoma of the breast and of the uterus and the urine of men and women without cancer for the 17-ketosteroids. The results show that noncancerous persons of either sex have a higher total 17-ketosteroid output and a definitely higher output of digitonin precipitable hydroxyketones than do cancerous persons. Furthermore, men without cancer excrete roughly twice as much of the 17-ketosteroid compounds as do women without carcinoma. This ratio held for all the fractions studied. On the other hand men and women with cancer tend to excrete approximately the same amount of neutral 17-ketosteroids. This was equally true for all the fractions analyzed.

- Traumatic Conditions of Wrist I G Hodgson Atlanta—p 66

**Epidemic Pleurodynia**—Fulghum states that, between July 15 and Sept 1, 1940, 28 cases of epidemic pleurodynia a rare or unrecognized condition in the South, occurred in Milledgeville and Baldwin County, Ga. The age of the patients varied from 13 months to 64 years. The cause of the disease is unknown. The intravenous injection of blood taken from patients in various stages of the disease to volunteers failed to reproduce the disease. The examination of stained blood films did not reveal any plasmodia. Every patient had pharyngitis. The symptoms suggest involvement of the diaphragm or the intercostal muscles, as the pain roughly follows the diaphrag-

matic attachment to the thoracic wall. The sudden onset, character and location of the pain, the short high fever and the recurrent paroxysms constitute a clinical picture not difficult to recognize. Complete recovery is invariable. Morphine is required to relieve pain. Codeine and acetylsalicylic acid are of little use in controlling pain. Quinine, thought to be specific, was extensively used but did not alter the course of the disease.

- Pituitary Antagonists in Treatment of Bronchial Asthma Estrogenic Therapy in Asthma E E Beard and W P Garver Cleveland—p 128

**Simmonds' Disease**—Escamilla and Lissner collected data on 595 cases suggesting Simmonds' disease through an exhaustive search of the literature, correspondence and their personal experience. In 101 of these the diagnosis was established both clinically and pathologically, and in 158 the clinical picture seemed typical but either the patients are still living or necropsy was not done. Many of the 158 may have been instances of anorexia nervosa. Of the rest of the cases, in 180 one or more of the cardinal clinical signs were lacking, in 43 the diagnosis seemed doubtful, in 15 destructive lesions of the pituitary body but no typical clinical signs were present, in 14 typical clinical signs but a normal pituitary were present and in 84 data were insufficient for classification. For purposes of comparison, 20 typical cases of anorexia nervosa were included. The most difficult problem is in differentiating between true Simmonds' disease and anorexia nervosa. Severe loss of weight and a low basal metabolic rate in a young unmarried woman who has never been pregnant favors the diagnosis of anorexia nervosa. A decided improvement or a return to normal health as a result of psychotherapy or after any treatment available at present (including endocrine therapy) further suggests this diagnosis. A claim of cure in any case of true Simmonds' disease is open to doubt unless a pituitary tumor has been removed successfully. Severe loss of weight, amenorrhea and a low basal metabolic rate in a woman of more than 30 years whose symptoms follow a postpartum hemorrhage and collapse or whose sella turcica is deformed or contains calcification and in whom in the course of the disease axillary and pubic hair is lost warrant a clinical diagnosis of Simmonds' disease. Psychopathic disturbances favor the diagnosis of anorexia nervosa but do not exclude Simmonds' disease.

**Testosterone Propionate Pellets**—Howard and Jewett implanted in the infrascapular region of 15 patients with hypogonadism uniform machine made testosterone propionate pellets. Absorption was rather rapid for the first few days after implantation, amounting to as much as 3 or more mg a day from each 200 mg pellet. After this, presumably with capsule formation absorption steadied down to a surprisingly constant daily rate between 0.5 and 1 mg, and this rate continued for many days, falling gradually until the pellet became very small. The dose must be individualized. Thus for a patient whose requirement for an adequate subjective effect is a minimum of 4 mg a day five pellets would be sufficient for a considerably shorter time than would be required for a patient whose required dose is

3 mg a day. Therefore, in a patient in whom five pellets have become inadequate in four or five months an adequate absorption level can be provided by implanting two more pellets. When a new implant is considered, seven or eight pellets might be more suitable than five. The five 200 mg pellets have been subjectively adequate for all the authors' patients to date for at least and usually more than three months. During the first week considerably more androgen is absorbed than is necessary, but no harmful results have been observed. The patients who have had implantation, injection and oral therapy have, with a single exception, preferred pellet therapy by implantation.

**Multiple Primary Malignant Lesions.**—Tullis reports 21 instances of multiple primary malignant lesions encountered at necropsy in 1,044 consecutive cases in which a malignant lesion was present. Each lesion possessed generally recognized malignant characteristics, the microscopic pattern of each was a distinct entity, metastasis having been ruled out as far as possible. Three of the forty-four lesions noted were sarcomas and forty-one were carcinomas. Twenty lesions involved the gastrointestinal system, two the skin, five the liver, four the prostate,

three the pancreas, three the lung, two the uterus and two the kidney. Metastasis from at least one of the lesions was present in 14 cases and metastasis from both lesions in 3. No metastasis could be found in 7. Seventeen of the patients were men and 4 were women, with an average age of 58.4 years. The average age is slightly above that for patients with single malignant lesions, thus lends credence to the opinion that the malignant tumor that appears late in life is less rapidly lethal than the one that appears early and that, being less rapidly lethal, such a tumor does not cause death before a second lesion develops.

**Histaminase by Intramuscular Injection.**—Vaisberg gave intramuscular injections of histaminase to 19 allergic patients. The usual maximal dose was 10 cc of histaminase solution prepared from fresh hog kidneys. At first the injections were given twice a week and later, if improvement ensued, once a week. All the patients were first tested to eliminate sensitivity to pork. As a tentative conclusion the author points out that the histaminase therapy may prove of value for resistant serum sickness, idiopathic pruritus and heat and cold allergy. It may be of limited value for neurodermatitis. Its effect on simple asthma was unpredictable, and it had no effect on vasomotor rhinitis, dermatographia, migraine and chronic urticaria. It was not tried in hay fever. Various lines of evidence lead to the impression that something other than the enzyme in histaminase is responsible for the improvement. Much more clinical work must be done with a potent, highly purified histaminase before any therapeutic claims for histaminase alone can be established.

**Sleep Paralysis.**—Lichtenstein and Rosenblum report a case in which sleep paralysis occurred in the first period of sleep with the patient completely paralyzed and unable to speak or move. Respiration was apparently unimpaired and continued as in sleep. The paralysis was described by Pavlov as a manifestation of localized sleep, with the motor centers "asleep" and "consciousness" awake. Sleep paralysis is frequently associated with narcolepsy, and attempts by some patients to ward off an attack precipitate an attack of helplessness. However, sleep paralysis accompanying natural sleep is a benign condition, probably resulting from a dissociation of the components of sleep. It should be differentiated from familial periodic paralysis. The patient should be assured that although the disorder is alarming, it is always of short duration and does not result in permanent paralysis or any other disease. Usually just a slight suggestion suffices to dispel sleep paralysis.

**Vitamins B and E in Tabes Dorsalis.**—Stone and Dancey report the results of the treatment of 18 patients with tabes dorsalis who had previously received intensive arsenical and heavy metal therapy without arrest of the progress of the disease. Sixteen of the patients were given thiamine hydrochloride intraspinally in addition to oral therapy with both vitamins. The patients received artificial fever therapy also during the spinal and oral therapy, and their improvement was noted. The patient who received no intraspinal therapy had no improvement. The patient who received no intraspinal therapy had ten inductothermy treatments one year previously, two concentrated arsenical and bismuth injections and oral vitamin complex therapy. No improvement occurred until vitamin B was administered simultaneously with the vitamin E. The rate of gain was less spectacular than that of patients

intraspinal treatment also but the improvement was definite after six weeks of treatment. Three patients with paraplegia showed some temporary improvement only while receiving intraspinal medication. The diplopia of a patient did not disappear after fever treatment and chemotherapy but was relieved by the first intraspinal injection of thiamine hydrochloride. His gait and disturbances of the bladder showed most improvement after he was given oral vitamin E and B therapy. Gastric crisis was not relieved when intraspinal medication was given during a crisis. Intraspinal and oral medication abolished gastric crisis of 1 patient for nearly a year; this patient returned to remunerative work. The intraspinal and oral treatment reduced but did not abolish the frequency of gastric crisis, and lightning pains were improved but did not disappear. Pupillary changes remained fixed, and abolished tendon reflexes did not return after treatment. The sense of vibration reappeared in several patients, and various paresthesias have either disappeared or have become a source of little discomfort.

**Sensory Disturbances Following Insulin Therapy**—According to Stern and his co-workers, a disturbance of the senses of taste, touch and smell were observed in 10 of 103 patients in the course of and for some months after insulin shock therapy. When sensory disturbances were observed the patients were given brewers yeast, but it is difficult to determine whether recovery was due to this therapy, as in 1 patient transient numbness and paresthesia were relieved by the administration of carbohydrate as soon as the patient awoke. A possible vascular cause for the disturbances particularly those of the extremities, must be considered. The problem seems to be similar to that of the damage to the central nervous system following hypoglycemia. Until more is known about the actual mechanism of sensory changes, insulin shock therapy should be supplemented by large doses of the vitamin B complex, which should be continued after the insulin course is completed.

**Encephalitis**—Eklund and Blumstein discuss the extensive epizootic of equine encephalomyelitis that occurred in Minnesota in 1938. 23,686 horses were reported as affected and 47 cases of encephalitis in human beings were reported to the Minnesota Department of Health. The onset in 36 cases took place between August 13 and September 20. The serum of 21 patients was tested for neutralization of the western virus. Fourteen of the specimens neutralized the virus, two neutralized

the St Louis virus and one showed moderate protection after standing in the ice box for two years. The distribution of patients whose serum neutralized the western virus was predominantly rural. The ages of these 14 patients varied from 1 month to 66 years. The typical onset was sudden, with headache and fever, and drowsiness appeared in a day or two. In the mildly affected patient no further symptoms appeared. In the more severely affected, drowsiness progressed to stupor, at times alternating with considerable restlessness. The sensorium became cloudy and there was disorientation in all fields. In about a week the temperature usually began to drop and a few days later the patient's condition began to improve. A stiff neck and, less frequently, tremors were practically the only physical signs. The acute phase of the illness lasted two to three weeks. Most of the patients had complete amnesia for the period of their severe illness. Examination of the spinal fluid revealed an increase of cells, the counts ranged from 30 to 400 cells. Seven of nine differential counts showed a predominance of lymphocytes and two a predominance of polymorphonuclear cells.

**Bronchial Asthma**—Shulman used phenytoin for the treatment of bronchial asthma in 7 children from 3 to 14 years of age. The patients had repeated frequent, acute attacks of asthma and a constantly "wheezy" respiration, that is, intractable asthma that had not responded to the accepted routine treatment. Each patient was first given 0.03 Gm of the drug morning and night. If after one week of therapy with this dose symptoms still persisted, the patient was given 0.03 Gm of the drug three times a day. The dose was increased by 0.03 Gm daily at intervals of one week until there were no attacks of asthma and no wheezing on moderate exertion. From 0.1 to 0.2 Gm of phenytoin usually kept the patient free from symptoms. After an adequate dose was arrived at 6 patients remained consistently free from attacks of bronchial asthma. The children were able to engage in normal athletic and social activities. Lack of parental cooperation and understanding was an important factor in the case in which benefit was not complete. There was a distinct change in the personality of 3 children, they became less irritable, their mentality improved and they were much easier to live with. A stubborn eczema of 2 children, which had persisted since infancy, cleared to a remarkable degree while the patients were being treated with phenytoin.

**Amebiasis**—Lewis and Low state that the microscopic examination over a period of five years of five hundred and eighty-six wet and stained smears of stools disclosed amebas in one hundred and twenty-six, an incidence of 21.5 per cent.

*Endameba histolytica* accounted for 57.14 per cent and *Endameba coli* for 26.19 per cent of the infected stools. The following factors probably explain the high incidence of amebiasis in and about the Yakima Valley: 1. The urban water supply of Yakima is purified by the chlorination sedimentation method, which is known to be ineffective against amebic cystic contamination. 2. Most of the rural water supply is derived from cisterns filled at intervals with irrigation water. 3. The unusually large number of orientals inhabiting the Yakima Valley, among whom the incidence of amebiasis is notoriously high, particularly in "carrier" form, is a contributing factor. The most common abdominal symptoms in the locale are flatulence and abdominal discomfort, and the most common constitutional symptoms are fatigue and nervousness. Suitable and varied treatments result in apparent cure in 90 per cent of cases.

**Ruptured Uterus**—Dugger analyzes the 105 cases of rupture of the uterus encountered among 318,103 live births and stillbirths in the county of Philadelphia during the last decade, an incidence of 1 ruptured uterus in 3,029 births. Only 1 of the 16 primigravidas recovered. All patients who had had seven or more pregnancies died. Most recoveries, 34 of 59, occurred among mothers who had had one to three previous pregnancies. There were only 6 other recoveries. The pregnancy terminated at or after the thirty-sixth week in 85 cases, and rupture occurred in 12 between the thirty-first and the thirty-fifth week, in 6 between the twenty-sixth and the thirtieth week and in 2 between the twenty-first and the twenty-fifth week. Fifty-six, or 86.1 per cent, of the deaths followed operative delivery. Internal podalic version was most frequently associated with rupture of the uterus. Fifty-five, or 84.6 per cent, of the deaths were preventable through improvement in the technical skill and judgment of the obstetrician, prompt and competent consultation in the presence of abnormal conditions, the termination of some vaginal or abdominal deliveries when rupture threatened, immediate laparotomy with hysterectomy or repair of a rupture when it had occurred (as the risk from infection is probably less than the danger from shock and hemorrhage) and the prompt and appropriate treatment of shock and hemorrhage.

**Chemotherapy in Infections of Upper Respiratory Tract**—From the results of the treatment of 50 patients with severe infection of the upper respiratory tract by the usual method and of 50 others who in addition were given one of the sulfonamide drugs, Davison concludes that: 1. The sulfonamide drugs are of value in severe acute sinusitis, tonsillitis, nonsuppurative cervical lymphadenitis and cellulitis of the neck. 2. To obtain maximal benefit the drug must be used in the first forty-eight hours of the disease and in an adequate dose. 3. The sulfonamide drugs should not be used for the treatment of ambulatory patients. 4. Frequent blood counts and urinalyses must be done. 5. Treatment with the sulfonamide drugs does not take the place of transfusion in streptococcal infections or of surgical drainage when tissue necrosis or suppuration is present.

**Liver Toxicity in Anesthesia**—Morrison and Swalm present a quantitative study of the postoperative hepatic function of patients after nine types of anesthesia. 1. The function of a normal liver under spinal anesthesia showed the least impairment and the most rapid return toward normal. The concentration of bile salt was depressed to only 760 mg on the first day, and by the seventh day it reached the minimal normal concentration, 1,500 mg. 2. Spinal anesthesia produced, in the presence of a pathologic condition of the liver, an average concentration of 480 mg of bile salt. Seventeen days later the average maximal concentration, 730 mg, was reached. 3. Combined ether anesthesia in the presence of a normal liver produced an average concentration of 520 mg on the first postoperative day, and in seven days the normal minimum, 1,500 mg, was reached. 4. In patients given combined ether anesthesia in the presence of a pathologic condition of the liver the average concentration was 250 mg on the first postoperative day, and only in eleven days did the level of bile salt reach that of the patients given spinal anesthesia. 5. Patients with a normal liver who were given evipal intravenously and underwent minor surgical procedures showed normal hepatic function immediately after the anesthesia as well as subsequently. 6. The hepatic function of patients with a normal liver who were given avrim with amylene hydrate rectally was definitely abnormal or depressed on the first and third postoperative days. 7. The hepatic function of patients with a normal liver who were given cyclopropane was not affected. 8. The postoperative hepatic function of patients with a normal liver who were given nitrous oxide anesthesia was normal on the first and subsequent postoperative days. 9. On the first and subsequent postoperative days the hepatic function of patients with a normal liver who were given spinal anesthesia was normal, as measured by the concentration of bile salt in the urine. Further study revealed that chloroform anesthesia as used for obstetric delivery is definitely toxic to the liver and can cause toxic hepatitis or subacute hepatic necrosis. The anesthetic should be used with utmost caution for obstetric delivery because of the slight impairment in hepatic function that occurs during pregnancy.

**Retained Testis**—Rieser cites a case of bilateral intra-abdominal testes in a boy of 17 and states that the case illustrates that intra-abdominal testes rarely descend spontaneously. Even at 17 the physiologic and psychologic improvement that the boy experienced as a result of surgical intervention proves that the operation was warranted. Glandular therapy, the author concludes, before the age of puberty is questionable and at puberty it is unnecessary. It has no harmful effect on a normally situated testis but a definite degenerative effect on the retained testis, and it may produce harmful constitutional changes. For cryptorchism associated with the Froehle syndrome glandular therapy is indicated before puberty.

Renal "Back Pressure" and the Enlarged Prostate—

On the basis of examining approximately 500 cases of enlarged prostate by intravenous urography Kraus concludes that prostatectomy to be successful must restore the normal evacuation of the urinary bladder decompress renal back pressure and cause the normal tonus and peristalsis of the renal pelvis and the ureter to reappear. The patient suffering from an enlarged prostate which has led to renal damage can be considered as 'cured' only if transurethral resection or some other procedure has achieved this. If postoperative intravenous urography of patients considered cured by transurethral resection reveals that satisfactory decompression of renal back pressure has not taken place, sooner or later suprapubic or perineal prostatectomy will lead in the radical surgical treatment of the enlarged adenomatous prostate. If it can be proved that hemiprostatectomy decompresses the kidney (when only one kidney is damaged) on the side of the adenoma, this conservative method will be preferable to radical procedures. The surgeon who performs a two stage suprapubic prostatectomy runs fewer risks than the operator who trusts functional tests which do not reveal dormant urinary infection and/or a grossly impaired ureteral peristalsis. These two factors can be evaluated only by intravenous urography, and that is why prostatectomy still seems a too hazardous operation. With intravenous urography renal back pressure can be diagnosed and too early prostatectomy excluded. With the aid of intravenous urography it is possible to recognize that the enlarged prostate is not only an obstacle to micturition but also an obstacle to normal ureteral peristalsis and tonus.

Relapsing Fever—As war, famine and epidemic diseases are bound together and relapsing fever (mothered by the louse) is a common scourge, Stannus and Bendit report its occurrence in a Belgian aviator who was admitted to the French Hospital on July 30, 1941 with a temperature of 103 F and a pulse rate of 84. He did not complain of any symptoms, and except for a dirty tongue and constipation abnormal physical signs were not present. The rise of temperature had been accompanied by shivering, and its fall to 98 F the next day was associated with profuse sweating and exhaustion. The temperature was normal four days later, remained so for a week and then began to rise. On the basis of a history of a previous febrile attack on July 13 which lasted for five days a diagnosis of relapsing fever was made and confirmed by examination of a blood film. No treatment was given. The patient's history revealed that he was shot down at the time of the Belgian collapse, escaped to France, entered Spain in an attempt to reach Portugal, was imprisoned in Spain from Oct 26 to Nov 10, 1940 then sent to a concentration camp from which he escaped on Feb 7, 1941, made his way back to unoccupied France, remained there until June 15, when he crossed to Spain, evading capture, and reached Lisbon on July 13, when he had his first attack of fever. During his wanderings and imprisonment he had suffered great privation. All the inmates of the prison were lousy. The patient does not recall being bitten by ticks. The incubation period of relapsing fever is commonly six to ten days but may be much shorter or longer. It is therefore probable that he was infected in Spain. The lack of severe symptoms is characteristic of the disease encountered in Spain, which is transmitted by ticks (*Ornithodoros maroccanus* and *exoticus*). It seems possible that the case is one of endemic relapsing fever, with the tick as the vector, rather than one of the epidemic type carried by the louse.

**Brucellosis and Tuberculosis**—According to Purriel and his collaborators a considerable literature exists on brucellosis and tuberculosis. It has been pointed out that brucellosis may be mistaken for tuberculosis, that the two concur and that the tissular and humoral reactions caused by them are similar. Brucellosis can take on the aspects of tuberculosis and simulate miliary tuberculosis, meningitis and various types of extrapulmonary tuberculosis. Some observers insisted that the endocrinologic state of patients with brucellosis favors the appearance or exacerbation of tuberculosis. "Brucellosis makes the bed for tuberculosis." The authors investigated the index of tuberculous infection in workers of meat packing plants, in whom infection with *Brucella bovis* had been detected by means of the intradermal reaction of Burnet, the tuberculous morbidity in workers infected with brucellosis and the tuberculous morbidity in workers who had had brucellosis. They concluded that the index of tuberculous infection is only slightly higher in workers infected with *Brucella bovis* than in the other workers of the meat packing plants. The tuberculous morbidity in the brucella infected employees was lower than that in the employees without brucella infection. The tuberculous morbidity in workers who had had brucellosis was not greater than that in the other employees. In a case in which tuberculosis and brucellosis coexisted, brucellosis was completely cured and there was no aggravation of tuberculosis. The authors disagree with the postulates that "brucellosis makes the bed for tuberculosis" or that tuberculosis is always aggravated in persons in whom brucellosis develops.

- \*Pulmonary Lesions of Malignant Lymphogranulomatosis M R Castex, A Pavlovsky and J Valotta —p 117  
Inactivation of Estrogenic Substances in Organism E Fels —p 140  
Pulmonary Atelectasis Caused by Aspiration of Residual Air A Bence and A Lanari —p 152  
\*Action of Bile on Acceleration of Jejunoileac Passage R Q Pasqualini and A J Burlando —p 174

**Pulmonary Lesions in Malignant Lymphogranulomatosis**—Castex and his collaborators report observations on 340 cases of malignant lymphogranulomatosis (Hodgkin's disease). A large number of the patients were under observation for only a short time, 74 were followed up during the whole course and 73 are undergoing treatment at present. In only 16 cases was invasion of the lung demonstrated in the roentgenogram. The pulmonary lesion was visualized from the beginning in only 3 of the cases.

**Action of Desiccated Hog Bile on Accelerated Jejunoileac Passage of Food**—Pasqualini and Burlando analyzed manifestations of accelerated jejunoileac passage in 100 cases. The general symptoms were emaciation, asthenia, fatigability, insomnia, mild fever, nervousness and mental depression. Digestive symptoms were manifested by anorexia, epigastric pain, eructations, heartburn, hyperchlorhydria, nausea, vomiting, periumbilical pain, meteorism, constipation or diarrhea. Vasomotor or neurovegetative symptoms were facial flushing, sweating, despondency, palpitations, dizziness and headaches. Examination of the feces disclosed lipolytic, amylolytic and proteolytic insufficiency and the presence of abundant cellulose. Blood analysis revealed macrocytic anemia. Paresthesias and anesthetic zones were noted in the extremities. In all cases the jejunoileac passage of food was much accelerated. Administration of desiccated bile to healthy persons caused a moderate retardation of the normal passage of the jejunoileac contents. In patients with accelerated passage the desiccated bile affected a considerable slowing of the jejunoileac passage

of food, so that the roentgenograms showed a normal behavior of the intestinal contents. Continued administration of bile to patients with accelerated jejunoileac passage counteracted the clinical manifestations.

- \*Observations on Antidiphtheritic Immunity J P do Amaral —p 131  
**Antidiphtheritic Immunity**—Do Amaral administered diphtheria anatoxin to 517 children from 6 to 14 years of age. The anatoxin was administered subcutaneously in doses of 0.1 and 15 cc at intervals of fifteen days. Four children exhibited a general and local reaction of general malaise, fever for twenty-four or forty-eight hours and local inflammation. In these cases the single injection which causes a general and a local reaction produces protection of the same degree as that which is obtained by the total treatment of three injections as given to nonhypersensitive children. The natural and acquired immunity was verified in 98 children and 55 children, respectively, by means of Kellogg's biologic test, performed before and three months after the injections. Natural immunity was found in 18 of 98 children. The specific anatoxin contents three months after vaccination were of high titers in 55 tested children. The results showed acquired immunity of high degree in all cases. Diphtheria anatoxin is harmless and of great antigenic power.

**Action of Thymus Hormone on Larvae of Cold Blooded Animals**—Bomskov and Kückes demonstrated that the diabetogenic hormone of the anterior pituitary is a thymotropic hormone which stimulates the production of a hormone in the thymus. This hormone is a lipid substance. Bomskov and his collaborators isolated it and explained its action. Their observations indicate that the thymotropic hormone of the anterior pituitary is probably identical with the growth hormone. From this it was deduced that the growth action of the pituitary is effected by way of the thymus. Bomskov and Kückes were able to demonstrate on frogs that the specific thymus hormone is capable of eliciting the same manifestation which other investigators had obtained in the feeding of fresh thymus to the larvae of cold blooded animals. The weight and the longitudinal growth of the frogs increase, and there are changes in the external form, such as spherical shape of the trunk, widening of the caudal fin and extremely dark pigmentation. The most important characteristic of the animals treated with thymus hormone is a complete inhibition of subsequent administration of thyroid. Whereas untreated control animals of the same spawn respond to the feeding of thyroid in the same known manner, tadpoles that have been treated with thymus hormone do not respond, neither shape, weight nor length of the animals is altered by the administration of thyroid. The antagonistic action of the thymus hormone on the thyroid is corroborated by the results of experiments conducted by Bomskov and Spiegel, who ascertained that in the basal metabolism of warm blooded animals also the thymus hormone acts as an antagonist of the thyroid. The results obtained with the fresh thymus substance, and it is suggested that the effects on the larvae of cold blooded animals are specific for thymus hormone.

## The Medical Student of Today

In America we are blessed by living in a country richly endowed, a nation producing 100 billion kilowatt hours of energy a year, or work equal to the human power of one-half billion men working eight hours a day. So never sell America short, no matter what happens in the rest of the world. What of the medical student? His greatest asset is health. Nothing can take its place. A smooth, efficient human machine is something devoutly to be wished and to guard. There are a method of living and a system of life which are conducive to that state. This demands systematic planning of work and recreation and exercise and diet and the avoidance of all factors which induce or favor disease. The modern student rarely learns to allocate these essentials in their proper places.

The next great asset is to become a master workman. Today we see fear abroad. There is only one thing that cannot be taken away from you and that is what you store up in your forebrains—the knowledge of your profession. No matter what the future, medicine is an essential commodity because it deals with the only real common denominator which determines the destinies of the world, and that is mankind itself.

These buildings are dedicated to the study of man. You are to be entrusted with the lives of men, women and children. Our business is to prepare you for that task. Some of the mistakes you will make in later life you can trace to your omissions in the classroom.

I have a few suggestions.

Have a plan. Where do you expect to go? Lay a course and stick to it now. In the first two years you should master the fundamentals, in the last two years you use those fundamentals. You must master them. How beautifully the pieces of the jigsaw puzzle fit together when the

whole course is mastered. You will learn modern medicine. It was my privilege to have as teachers Vidal, who discovered the Vidal reaction, Laveran, who discovered the malarial parasite, Roux, one of the assistants of the immortal Pasteur, and a number of those great men who in the latter part of the last century welded some of the links to make the mighty thing called medicine today, but none of them possessed the weapons against disease that you will possess.

Begin now the student habit. Medicine is rich with adventure. The impenetrable jungle is giving up its secrets day by day. Some day the spark may jump from a book or a magazine or a teacher and ignite you, and then suddenly you realize that you too have some of those qualities which made other men great in their chosen fields.

You never know what you can do until you try. The great French neurologist Pierre Marie pointed out that none of us use the full capacity of our minds. He said that many of the cells were in a state of atrophy from disuse. Nearly every great man I have known has had some physical infirmity or some mental complex to overcome before he could bring his full faculties into play.

Medicine today is founded on all that has gone before. Chemistry has not hesitated to knock at the very principle of life itself. Physics has not hesitated to shatter the atom. The electron microscope and the spectroscope foreshadow new things. We cannot afford to remain static. He who charts his course and will not allow himself to be diverted and uses every energy to reach his goal will rarely fail. Energy, dissatisfaction with existing conditions, a ceaseless striving after perfection reward the toiler with more muscle, more strength to climb.

There are few successes without some failure and few failures without some successes. To one man failure spells the end of everything, to another it only serves to spur him on. Few

jobs fail to respond to the ceaseless biting off piece by piece

Finally a great school has first morale, then discipline and, last but not least, loyalty. Morale implies self respect and a healthy mind in a healthy body. Discipline implies respect to constituted authority and a consciousness of the purpose of our work, loitering in the hallways, putting your feet on the benches, talking when some one else is talking, residents who sit at the table when the Chief enters, nurses who are careless and noisy, patients who are unkempt,

beds poorly made, wards littered with apparatus no longer needed, histories incoherent and illegible, all attest lack of discipline. In the absence of the Chief, the resident is literally the subchief and so responsible for discipline and order.

To paraphrase a British statesman in his finest hour, we shall fight disease wherever we find it by every means in our power, in the hills, in the country, in the homes. We shall learn all the methods of organized science to combat disease. We must never falter.

## The Psychologic Examination

In medical school the student receives careful training in the technic of making a physical examination. Inspection, palpation, percussion and auscultation become almost second nature to him. He spends many hours in learning the methods of chemical examination as applied to the fluids of the body. But about the technic of the psychologic examination of the patient he is taught practically nothing. In medical practice he soon finds that it is often as necessary to make a psychologic examination as it is to make a physical examination, but because of his lack of training and his unfamiliarity with the technic of a formal procedure he can do so only haphazardly.

Many physicians do not even know that there is an established technic of psychologic examination, although it has been in use by psychiatrists for forty years under the misleading title of the "mental examination." Now that physicians in other fields of medicine are more generally aware of the necessity for psychologic examinations and the usefulness of a standard procedure, it seems appropriate to give the widest possible circulation to any scheme which has proved useful.

The psychologic examination used in psychiatry is based on the assumption that there are certain intellectual, emotional and behavior patterns characteristic of the individual which can be observed, recorded and compared with those of other persons, and the concurrences and dis-

crepancies indicated. Some of the reactions can be measured approximately, others of them quite accurately. The order in which data are collected and the details investigated in the exploration of the various fields of mental activity have varied in different psychiatric clinics. A scheme has been worked out over a period of twenty years at this clinic. The procedure has been changed many times, in fact, it is constantly being modified and, we hope, improved.

For the sake of completeness the entire procedure of examination and testing is given. These are only suggestions, and the examiner must use his judgment in modifying them for the individual patient. Although the outline should be followed rigorously in recording and organizing the data, it is rarely practicable to follow it systematically in obtaining them. It is generally best to begin by asking the patient to tell how he came to be there and from this go on to the life story, later filling in omissions in the family history, developmental history, school history and the vocational, sexual and religious history.

In actual practice the young psychiatrist in training carries through the entire investigation as outlined. The inexperienced examiner will need to take specific notes regarding his observations and the data supplied by the patient, but the experienced examiner may be able to record mentally sufficiently vivid and accurate impressions to enable him to dispense with note taking and rely on his memory when he later dictates the material.

The introduction to an outline of procedure for determination of the mental status of the psychiatric patient by Drs. William C. Menninger, Karl A. Menninger and Robert P. Knight, published in the Bulletin of the Menninger Clinic, July 1941.

## DO YOU KNOW WHAT PHYSICIAN—

Was the first Surgeon General of the United States Navy and the fifth chief of the Bureau of Medicine and Surgery?  
(The answer will be found on page 305)

## Medical College News

### Air Raid Precautions at Harvard

All the resident students at Harvard Medical School, Boston, have been assigned to posts at the school or at some nearby hospital in the plan of preparation against possible air raids. According to *Pulse*, March 9, which the New England Regional Committee of the Association of Internes and Medical Students just started publishing, the duties assigned to the Harvard students in this precautionary program range from that of roof watcher to first aid worker with regular drills scheduled. All third and fourth year medical students have already qualified as first aid instructors.

### Student Finances and the Accelerated Course

Now that summer sessions in many schools will keep students from the usual summer gainful employment, the New England region of the Association of Internes and Medical Students sent questionnaires to medical students of Boston to learn how many would need financial help in order to continue their summer studies. Four hundred and twenty-one students of the freshman, sophomore and junior classes returned the questionnaires and of these 60 per cent said they would require on an average \$360 more than they had to carry on. These students made on the average during the last summer vacation \$320.

### Yale's First Wartime Doctors

The majority of the fifty-one members of the graduating class at Yale University School of Medicine, New Haven, Conn., are already registered for military service and expect to be in active duty with the armed forces after completing the year of internship allowed by the Army and Navy. Yale's first wartime doctors have already received internship appointments to hospitals in fifteen states, Dean Francis G. Blake announced May 1. Yale University School of Medicine will embark on an accelerated year-round program, beginning June 29, when the entering class will be increased by 20 per cent to help meet the war emergency. At least sixty students will be admitted to the school in June instead of the customary fifty.

### Indiana Cancels Postgraduate Courses

According to the Indianapolis *Star*, the Indiana University Medical School, Indianapolis, has canceled all but one of the postgraduate courses held each spring at the University Medical Center for the duration of the war. Dean Willis D. Gatch is reported to have said that, although hundreds of general practitioners have been attending these courses each spring, the committee in charge agreed that the demands being made on the profession as a result of the war situation make it impractical to continue the courses at this time. The one postgraduate course which has not been canceled is the annual course for specialists in eye, ear, nose and throat diseases, which is attended annually by physicians from widely separated sections of the country.

### Annual Undergraduate Day at Pennsylvania

The University of Pennsylvania School of Medicine, Philadelphia, held its annual Undergraduate Medical Association Day on April 9. The entire school day was given over to special addresses and student research reports. Among others, Dr. O. H. Perry Pepper spoke on the medical student and the war, Dr. Franklin C.

McLean of the University of Chicago on "War Gases," and Dr. Carl J. Wiggers of Western Reserve University School of Medicine, Cleveland, on "Recent Developments in the Study of Shock."

### More British Medical Students Study in the United States

Again the Rockefeller Foundation has offered twenty-five studentships to medical students in England to enable them to take part of their clinical courses in medical schools in the United States and Canada. While the object primarily is to help students in schools which have been bombed during the war, applications from all medical schools in England, Scotland, Wales and North Ireland may be made. The studentships are for two years or possibly a shorter period in special cases and, subject to satisfactory progress, cover all tuition fees, maintenance and so on but not the cost of travel to and from America. The students must return to their own country to take their final examination. The successful candidates for the twenty-five studentships will probably leave England in August, although applications were to have been in not later than April 25, accompanied by a full and confidential report by the dean, a medical certificate and a roentgenogram of the chest. Candidates must be willing to comply with certain conditions as regards vaccination.

According to the *British Medical Journal*, the medical schools at the following universities are prepared to take one or two of these students: California, Chicago, Cincinnati, Columbia, Cornell, Duke, Harvard, Illinois, Iowa, Johns Hopkins, McGill, New York, Pennsylvania, Rochester, Stanford, Toronto, Tulane, Vanderbilt, Washington, Western Reserve, Wisconsin and Yale.

An item concerning the first group of British medical students who came to the United States to study was published in the Student Section on Dec. 27, 1941, page 2288.

### Winners of the Schering Award

The Association of Internes and Medical Students has announced the following winners of the 1941 Schering Award: Fred Feldman '42, Albany Medical College, and Cesare Lombroso Jr. '42, Johns Hopkins Medical School, have been awarded first and second prize, respectively, Elizabeth L. Brown '44, Albany Medical College, and Clarence Denton '44, Long Island College of Medicine, have been awarded third prize. The subject of the competition was "The History of Endocrine Research."

This award was established by the Schering Corporation and is conducted by the Association of Internes and Medical Students. It provides two tuition scholarships of a year and a half year, respectively, for the best papers on some aspect of endocrinology submitted by medical students in the United States or Canada. In this contest, papers were submitted by students representing twenty-four medical schools.

The committee of judges included Drs. Edward C. Hamblen, Duke University School of Medicine, Roy G. Hoskins, Memorial Foundation for Neuro-Endocrine Research, Harvard Medical School, Herbert M. Evans and Hans Lissner, University of California Medical School, Ernest P. McCullagh, the Cleveland Clinic, Emil Novak, University of Minnesota School of Medicine and College of Physicians and Surgeons, Elmer L. Scoville, University of Wisconsin Medical School,

Ephraim Shorr, Cornell University Medical College and the New York Hospital, and Fried C Koch, Ph D, and Carl R Moore, Ph D, University of Chicago

#### Speed Instruction at Western Reserve

In conformity with the nationwide movement to speed medical instruction so as to prepare more physicians for the urgent needs created by the war, Western Reserve University School of Medicine, Cleveland, announced early in the year that it would eliminate the summer vacation and begin its next session on June 22 and then start new classes at intervals of about nine months for the duration of the emergency. An extensive study of the situation indicates that four continuous sessions of thirty-six weeks, arranged as semesters, appear necessary and sufficient to maintain the desirable standards. In the first, second and third years, these comprise thirty-two weeks of instruction, two examination weeks and a recess of two weeks at the end of the second semester. The fourth year consists of thirty-five weeks of clinical clerkships and a week for commencement. The entire course would thus be completed in one hundred and forty-four weeks. New classes according to this plan would begin on June 22, 1942, March 1, 1943, Nov 8, 1943, July 17, 1944 and March 26, 1945. The entire program will be subject to change with developments. In view of the various programs of acceleration adopted by the undergraduate colleges, it is impossible to devise an integration of premedical and medical courses that would be universally applicable without any interruption. However, the elasticity of the electives in the undergraduate courses should make it possible to complete the subject requirements, if they are planned well in advance. The bachelor degree requirement may be waived during the emergency in the case of exceptional students who have completed at least three years of college work.

#### New Chapters of Sigma Xi

Three new chapters of the society of the Sigma Xi, national honorary society for the promotion of research in science, were installed during March. In the installation of a chapter on March 14 at Utah State Agricultural College at Logan, John G Kirkwood, professor of chemistry at Cornell University, gave an address on "The Structure of Liquids."

At the Illinois Institute of Technology, Chicago, March 25, a chapter was installed with Ross A Gortner of the University of Minnesota, president of Sigma Xi, and George A Baitzell, Yale University, secretary of Sigma Xi, as the installing officers. The day was marked by a general assembly of students, inspection of laboratories and an installation dinner at which H A Bethe of Cornell University spoke on "Energy Production in Stars."

A Sigma Xi chapter was installed with appropriate ceremonies on March 24 at the Louisiana State University, Baton Rouge.

#### Louisiana University

Joseph T Stansfield '42 was elected president of the Louisiana State University Society of Medical Sciences at the last meeting of the school year, May 7, Francis L Ware '42, vice president, and George B Payne '42, secretary-treasurer. The faculty adviser elected was Dr Karl Dickens of the department of medicine. The chairman of the banquet that followed the meeting was the outgoing president of the society, Connie I Hood Jr '41. At a recent meeting, Louis Lazar was chosen the outstanding senior member of the organization, the textbook "Pharmacological Basis of Thera-

peutics," by Goodman and Gillman, was presented to him by the society at a banquet, February 4. At the meeting of the society, March 9, papers on "The Therapeutic Uses of the Vitamins" were presented by Philip Dann, Herbert Tucker, George Whitman and R V Marlin. The discussion was opened by Dr John LaDue of the department of medicine. The society was addressed, March 16, by Mr Francis LaTard on "History of Hernia Repair," followed by a motion picture on the surgical repair of hernia and a discussion by Dr Hugh C Ilgenfritz, the organization's faculty adviser. Gordon Peek was elected president of the student body of the Louisiana State University School of Medicine, New Orleans, for the present year.

#### Wayne to Build a Student Center

The board of education of Detroit on March 24 approved a competitive program for an architectural design and campus arrangement for the proposed extension of the Wayne University campus and for the selection of an architect for a student center building. A group of five persons, including three architects, will select the winning design. There will be cash awards totaling \$4,000, and the winner of the student center building portion of the contest, who may or may not have been awarded one of the other prizes, will receive \$2,275, which will be a payment on account of the total of 5 per cent which the person will receive after construction begins. The first block in the proposed expansion of the university campus is already under condemnation. The actual construction, however, of the student center building will await the termination of the war. Wayne University officials have had the expansion program under discussion for several years. This program is independent of the one being considered for the proposed Wayne University Medical Center.

#### Harvard Awards Scholarships

Harvard Medical School, Boston, announced the award of scholarships and fellowships to the following medical students, April 9, totaling \$6,100.

To Robert Paine, Memphis, Tenn., the David Williams Chever Scholarship. To Sheridan S Evans, Iuka, Ill., the Charlotte Greene scholarship. To Lyndon R Barnett, North Stratford, N H., Albert C Biegel, Denver, Edward L Burwell, Porterville, N Y., Harvey R Butcher, Adrian, Mo., John W Harris, Allston, Mass., Felix Heimberg, Dorchester, Mass., Peter J Koeniger, Woodhaven, N Y., Paul J R Schlessinger, Pawtucket, R I., Chandler A Stetson Jr, Brunswick, Maine, Arthur W Trott, Wollaston, Mass., and Edward P Wallace, Newton Center, Mass., the George Haven Scholarships. To John E VanderLaan, M D, Muskegon, Mich., the Jeffrey Richardson Fellowship. To Walter E Knox, McCook, Neb., the James Jackson Cabot fellowship. To John M Weller, Ann Arbor, Mich., the George Cheyne Shattuck Memorial Fellowship. To Arthur C Guyton, Oxford, Mass., the Charles Lindbergh Ware Memorial fellowship. To Israel H Schenker, New York, the John Ware Memorial Fellowship. To Robert L Berg, Spokane, Wash., Avram S Goldstein, New York, Irving M London, Malden, Mass., and Roger W Morrison, Pittsburgh, the DeLamar Student Research Fellowships.

#### Lecture at North Carolina

Dr George W McCoy, director of the department of preventive medicine and public health, Louisiana State University School of Medicine, New Orleans, during the week of February 16-20 lectured on leprosy and tularemia at the School of Public Health at Chapel Hill, N C.

## University of Cincinnati College of Medicine

Although its early history goes back to 1819 when the Medical College of Ohio was founded, the University of Cincinnati College of Medicine, as such, dates from 1917. The Medical College of Ohio united with the Miami Medical College in 1857. The schools separated in a few years but again united in 1909 under the name of the Ohio-Miami Medical College, and this school in 1917 became the University of Cincinnati College of Medicine.

The plant of the University of Cincinnati College of Medicine includes the college-hospital group of buildings, the Children's Hospital, the Chronic Disease Hospital and the Hamilton County Tuberculosis Hospital. The Children's Hospital is a complete unit for the practice and teaching of pediatrics, its medical director is the professor of pediatrics in the college of medicine. The Children's Hospital Research Foundation, which is a gift from the late William Cooper Procter, has extended the research and teaching facilities of the department of pediatrics. At the Hamilton County Tuberculosis Hospital, all senior students receive instruction in the treatment of tuberculous patients. At the Chronic Disease Hospital of Hamilton County 7 miles north of the medical college a course in geriatrics is offered as an elective to the senior class.

The Cincinnati General Hospital, the buildings of which are shown in the illustration (No. 1 to No. 21

inclusive) occupies 27 acres of ground. The chief of staff is the dean of the college of medicine. The hospital staff comprises members of the faculty of the college of medicine. The Holmes Hospital is a memorial to the late Dr. Christian R. Holmes under whose influence and leadership the campaign to build a new city hospital and medical college was carried out. The Holmes Hospital provides for the care of private patients and its professional privileges are restricted to the faculty of the college of medicine. Among the other facilities of the school is the Longview Hospital for the Insane, where classes in psychiatry are conducted during the first three months of each year. The Child Guidance Home is also used for teaching psychiatry. The medical school is represented on the Council of Social Agencies and is intimately associated with all the welfare organizations of Cincinnati.

Several libraries are available to medical students, the library of the College of Medicine, the library of the Cincinnati General Hospital one of the finest collections in the Midwest, the general library of the University of Cincinnati, the Library of the Children's Hospital Research Foundation, the Library of the William G. Merrell Company, the Charlotte R. Fischer Library and the Library of the Biological Chemistry Department. The Lloyd Library, which is available to research workers, is the private library of the late Dr. John Uri Lloyd and Mr. C. G. Lloyd, which con-

tains more than 30,000 volumes, many on pharmacology and pharmaceutical chemistry

Candidates for admission to the freshman class of the University of Cincinnati College of Medicine must have finished three years of college work. Students who are legal residents of Cincinnati are charged \$485 tuition a year, students who are not legal residents of the city are charged \$535. A person is not considered a resident unless he has been a bona fide resident of the city for one year preceding the date of his enrolment. A student remains a nonresident even though he has been in the city one year so long as his parents have not established residence in Cincinnati. There is also a student activity fee of \$10 for freshmen who do not possess an undergraduate degree, a breakage fee for freshmen and sophomores of \$15 and for juniors \$10. Each student at the beginning of the first semester of the freshman year must provide himself with a microscope.

The faculty has 462 members, of whom 147 are professors, associate and assistant professors and 315 instructors.

The college of medicine, while a part of the municipal university, does not receive any funds from taxation, it is dependent on the income from its endowment and from tuition fees for its budget.

#### Washington University

The seventh annual Leo Loeb Lecture, sponsored by the chapter of Phi Beta Pi fraternity at Washington University School of Medicine, St. Louis, was delivered, March 23, by Dr. John H. Musser, professor of medicine at Tulane University School of Medicine, New Orleans, on "The Heart That Is Getting Old." The psychology seminar group at this school was addressed on March 16 by Heinrich Kluver, Ph.D., of the University of Chicago, on "Recent Investigations on Brain Mechanisms and Behavior," illustrated with moving pictures.

The summer quarter will begin on July 11 for the freshmen, who will then continue on into the fall quarter without vacation. The upper three classes will register on June 13 and will have brief vacations in August and September.

#### Course in Medical Physics at California

The University of California has instituted a course in medical physics for undergraduate students, designed to teach the medical and biologic aspects of the sciences growing out of the atom smashing cyclotron and to teach research men in various fields how to use this new scientific tool. The course is given under the auspices of the department of physics, and the lecturers are members of the Radiation Laboratory staff. A new Medical Physics Building in which scientists experimenting with cyclotron products will work is nearing completion on the Berkeley campus. The cyclotron was developed at the University of California.

#### Indiana Fraternity Sponsors Lecture

The chapter of Nu Sigma Nu fraternity at Indiana University Medical School, Indianapolis, sponsored a lecture at the James Whitcomb Riley Hospital which was delivered by Dr. Charles G. Johnston of Detroit on "Control of Distention in the Therapy of Intestinal Obstruction." Preceding the lecture a dinner was given in honor of Dr. Johnston, the faculty members and presidents of the medical fraternities and the following guests: Dr. Maynard A. Austin of Anderson, president of the Indiana State Medical Association, and Dr. Carl H. McCaskey, Indianapolis, president-elect.

#### Alpha Omega Alpha at Cornell

The chapter of Alpha Omega Alpha, honorary medical society, at Cornell University Medical College, New York, held its initiation banquet, March 12, at the Hotel Wellington. Dr. Thomas H. Ham of the Boston City Hospital spoke on "Pathological Mechanisms in Hemolytic Anemia." The following were elected members of the society this year:

O. Whitmore Burtner Jr., New York  
Bruce M. Esplin, Miami Beach, Fla.  
William A. Geohagan, Dayton, Ohio  
Vincent A. Goiman, Kingston, N. Y.  
Culton C. Hunt Jr., New York  
Katherine W. Swift, Whitinsville, Mass.  
W. Francis Whitmore, Amityville, N. Y.  
Robert D. Deans, Ridgewood, N. J.  
Francis S. Greenspan, Perth Amboy, N. J.

#### History of Medicine Society at Tulane

The History of Medicine Society at Tulane University of Louisiana School of Medicine, New Orleans, held its ninth annual meeting in Hutchinson Memorial Auditorium on May 6, together with the Medical Library Association. Dr. Abraham Levinson of Chicago gave an address on "Medical Medallions." At the banquet of the History of Medicine Society preceding this meeting H. S. Mayerson, Ph.D., of the department of physiology at Tulane spoke on "Cultural Pursuits of the Physician." The Rudolph Matas prize for the best student essay was presented by Dr. B. Bernard Weinstein to J. V. Schlosser, a senior, and the Lemann Prize for the best student discussion to Winston C. Hibner, a senior. Dr. Harold Cummins of the department of anatomy spoke on the history of medicine. Walter Trautman Jr. was toastmaster.

#### The Wyckoff Lectures

Dr. Richard P. Strong, professor emeritus of tropical medicine, Harvard Medical School, Boston, delivered the fifth series of the John Wyckoff Lectures at the New York University College of Medicine, New York, March 24-25, on "Tropical Diseases and the War." The lectures were established by the Phi Delta Epsilon fraternity in 1937 in memory of the late Dr. John H. Wyckoff, who at the time of his death was dean of New York University College of Medicine.

#### Annual Undergraduate Day at George Washington University

The Undergraduate Medical Association of George Washington University School of Medicine, Washington, D. C., held its fourth annual student day meeting for the presentation of student research on April 18. All medical classes were suspended in favor of the meeting. The guest speaker was Major W. Randolph Lovelace, Medical Corps, U. S. Army, director of physiologic research and consultant in surgery, Army Air Corps, who discussed the medical aspects of high altitude flying.

#### Charter Members of Honorary Society

Seven senior students of Wayne University College of Medicine, Detroit, in recognition of their scholarship, have been named charter members of the newly installed chapter of Alpha Omega Alpha, honorary medical society. Those named are John G. Bielawski, Richard E. Bower, Herbert W. Devine, James R. Dols, Charles J. France, Donald B. Jury and Donald R. Simmons. Future membership in the society will come from the senior class each June, the highest ranking 10 per cent being eligible.

### Harvard Students Survey Curriculum

A committee of students from all classes at Harvard Medical School, Boston, under the chairmanship of senior student Tom Perry and sophomore student Jack Cannon, has been gathering constructive student criticism of courses to aid the faculty in making changes in the curriculum. Some years ago a curriculum survey was made by a group of students. The results were welcomed by the faculty and many of the courses ordered changed to conform with the student opinion.

### Fraternity Sponsors Snow Miller Lectures

Dr Edgar M End, Wauwatosa, Wis., instructor in physiology at Marquette University School of Medicine, delivered the fifteenth annual William Snow Miller Lecture on March 24 in the Service Memorial Institute, University of Wisconsin Medical School, Madison, under the auspices of Phi Beta Pi. His subject was "Recent Advances in Our Knowledge of Respiration and Their Application in Respiration Therapy."

### Dr Herbert Evans to Deliver Sigma Xi Lectures

The society of the Sigma Xi, of which George A Butsell, Yale University, New Haven, Conn., is secretary, announces that Dr Herbert M Evans, director of the Institute of Experimental Biology, University of California, Berkeley, will deliver a Sigma Xi lecture on the pituitary gland in about nineteen colleges and universities between March 24 and May 18.

### Dr Spies Lectures to Premedical Students

Under the auspices of the University of Alabama chapter of Alpha Epsilon Delta, national honorary pre-medical fraternity, Dr Tom D Spies of the University of Cincinnati College of Medicine recently lectured on "Pellagra and Other Diet-Deficiency Diseases in the South" before the students at the University of Alabama, University. Dr Spies is head of a research group now working at Hillman Hospital, Birmingham, Ala.

### Larger Freshman Class at Wayne

Wayne University, Detroit, announces that the college of medicine, which usually has no summer session but operates on a straight academic year system, will admit a new freshman class June 22, with provisions for seventy-five entering students instead of the customary sixty-five. Medical students will begin another academic year early in 1943.

### Lecture to Premedical Students

The premedical students at the Louisiana State University, New Orleans, were addressed recently by Dr Beryl I Burns, dean and professor of anatomy at Louisiana State University School of Medicine, New Orleans, on "the Position of Premedical Students in Relation to the National Emergency." The lecture was sponsored by the honorary premedical fraternity Beta Tau Mu.

### The McCoy Lectureship

Dr Arno B Luckhardt, professor of physiology at the University of Chicago School of Medicine was the speaker at the annual McCoy lectureship at Louisiana State University School of Medicine, New Orleans, February 15. The subject was "William Beaumont and the Medical Epic of the Northwest Territory." This lecture, in honor of Dr George W McCoy, is sponsored by the local chapter of Phi Beta Pi.

### Increased Enrolment at Indiana

The freshman class at Indiana University School of Medicine, Bloomington, is said to be the largest in several years. The class selected last spring by a committee of twelve faculty members numbered one hundred and forty, an increase of ten to help meet the demands being made on the medical profession by the defense program.

### New York University

The Student Council of New York University College of Medicine, New York, has established a periodical called *Newsletter*, in which it was said that the council has established a committee on defense activities, with representatives from each class and organization in the medical school. The committee will act as a liaison to bring together ideas on student defense and to put approved plans in operation.

### Senior Wins Award

George D Cummings, a senior at Wayne University College of Medicine, Detroit, has won the annual Walter J Wilson I Award for his paper entitled "Natural Immunity to Diphtheria," which was based on the incidence of diphtheria among children in state institutions. This award is presented annually to the Wayne student whose paper based on original research is adjudged the best for the year.

### "DO YOU KNOW WHAT PHYSICIAN"

Following is the answer to the question appearing on page 300.

William Maxwell Wood (1809-1880). An act of Congress of March 3, 1871 provided that the "chiefs of the Bureaus of Medicine and Surgery shall have the relative rank of commodore, while holding said position, and shall have respectively the title of surgeon general." Dr Wood was born in Baltimore and appointed assistant surgeon in the Navy in 1829. According to Capt Louis H Roddis, M C, U S Navy, in his paper in the *Military Surgeon*, March 1942, Dr Wood served in the Navy during the period concerned with the suppression of piracy, the slave trade, the Seminole War and the Mexican and Civil wars. His book "Wandering Sketches" gave an account of his travels. He was appointed chief of the Bureau of Medicine and Surgery by President Grant in 1869 and was retired for age on May 27, 1871. He continued to hold office as surgeon general until October 25 of that year and after ceasing to be surgeon general was employed until April 1, 1873 as medical inspector general of hospitals and fleets. Dr Wood had a vigorous intellect, force of character, strong common sense and perseverance for any measure likely to improve the well-being of officers and men of the Navy. Among other tours of foreign duty he accompanied a squadron of naval vessels in 1856 concentrated at Hong Kong to protect American interests. An attack was made on the forts below Canton, China. Dr Wood cared for the wounded after this engagement in a hospital in Hong Kong, where it was necessary to land marines to protect the wounded. At this time the European owner of a bakery attempted to poison the people of Hong Kong by placing arsenic in bread that was made in his bakery. Thousands were thus poisoned, but Dr Wood escaped as he ate bread from another source. All his patients became ill with arsenic poisoning, but none of them died. Dr Wood died at his home in Owings Mills in Baltimore County, Md.

## Book Notices

**What Are the Vitamins?** By Walter H Eddy, Ph D, Professor of Physiological Chemistry, Teachers College, Columbia University, New York. Cloth Price, \$2.50. Pp 247, with illustrations. New York: Reinhold Publishing Corporation, 1941.

To a large extent investigators have not been kind to their readers. In a rapidly developing field particularly it is often impossible for a practitioner to obtain the information he wants without the sacrifice of an inordinate amount of time and energy. For the persons who desire to acquire a working knowledge of the vitamins, the present book will be useful. There are brief summaries of each of the important vitamins and there are selected references in the bibliography of each chapter. The value of the book is enhanced by the inclusion of a table of the vitamin values of foods and by a list of different vitamin units and their equivalence. There also is a list of vitamins that have been chemically identified and those which have been characterized on the basis of physiologic evidence but which have not yet been isolated or identified chemically. The author has succeeded in the difficult task of condensing the story of the vitamins without sacrifice of accuracy.

**Aids to Anæsthesia** By Major Victor Goldman L R C P, M R C S, D A, Anæsthetist, Queen Mary's Hospital Stratford. Cloth Price, \$1.75. Pp 235 with 58 illustrations. Baltimore: Williams & Wilkins Company, London: Baillière, Tindall & Cox, 1941.

This pocket size manual is published as a contribution to a "students' aid series" for "English students in grouping and committing to memory subjects upon which they are to be examined," while offering to the English general practitioner a means of "brushing up" on a special subject. The preparation of an abbreviated or "outline" treatise on any subject is recognized as one of the most difficult tasks in medical writing. Major Goldman is to be congratulated on having covered a great deal of ground in this new addition to the students' aid series. For the American physician, who in the present world conflict may be assigned to duty in anesthesia with British forces, this addition to the series will prove invaluable. It offers briefly and in an easily assimilable form information as to differences in methods for the relief of pain current in British practice. Popular technics are described in detail. The appendix contains useful tables of equivalents and other data highly practical and time saving, especially to an American physician not familiar with British practice and British nomenclature. Minor variations in the concepts of fundamental principles and of technical applications held by British physicians, as compared with American, are evident. However, the sentence at the beginning of the preface, quoted from an American physician, "No anesthetic agent is safer than the person who employs it," probably expresses the feeling of all anæsthetists everywhere. Styles in the details of practice, like those in women's hats, vary with different seasons and different countries. As an aid to anæsthetists in either civil or military practice in America, Goldman's book will prove of limited value. The anæsthetist practicing in the United States will, however, appreciate it as an invaluable reference work which will answer questions arising in the course of his reading of current literature of British origin.

**Gynaecological Operations** By J Lyle Cameron M D, F R C S, F A C S, Senior Gynaecological Surgeon, Royal Waterloo Hospital, London. Cloth Price \$5.50. Pp 200 with 26 illustrations. New York & London: Oxford University Press, 1941.

The author states that the purpose of this book is "to present the technic of gynecologic operations as clearly and concisely as possible, giving the indications and contraindications and pointing out difficulties, dangers and complications against which the surgeon must be warned." This he has accomplished, if it can be accomplished, in the close space of two hundred pages. The use of radium is not discussed, but other ordinary gynecologic procedures are dealt with in proper proportion. One wishes more illustrations had been possible. This is a good

book, there is no doubt of that. It is harder to decide just whom the book will be good for. An experienced gynecologist will hardly require it, a student gynecologist needs a more extensive treatise. It is too advanced for medical students or nurses. The volume may be especially useful to the general surgeon who wishes a quick review of some gynecologic procedure before undertaking it.

**The Public Health Nurse in Action** By Marguerite Wales, R N, F A P H A, Nursing Education Consultant, W K Kellogg Foundation, Battle Creek, Michigan. With a foreword by Lillian D Wald. Cloth Price \$2.75. Pp 437, with illustrations. New York: Macmillan Company, 1941.

This tells what public health nursing is by a series of case studies drawn from all the varied types of service—maternity, infant and preschool, school, communicable diseases, tuberculosis, orthopedic, venereal disease, industrial and the care of the chronically ill. Under each special service discussed there is an analysis of the problem and the progress made to date toward its solution. This discussion is made graphic by the inclusion of well told case stories. The responsibilities of the public health nurse to the family in its entirety are stressed, and each case story emphasizes her effort toward attaining the objective of greater family independence, social and economic. In every instance the case stories are success stories and, while the author points this out in her introduction, one cannot but get a feeling of the Horatio Alger as one reads. Perhaps after Dr Derryberry's various treatises on the subject, this emphasis on accomplishment is heaven sent.

**The Avitaminoses: The Chemical, Clinical and Pathological Aspects of the Vitamin Deficiency Diseases** By Walter H Eddy, Ph D, Professor of Physiological Chemistry, Teachers College, Columbia University, New York, and Gilbert Daikdorf M D, Pathologist to the Grasslands and Northern Westchester Hospitals, Westchester County, New York. Second edition. Cloth Price, \$4.50. Pp 519, with 69 illustrations. Baltimore: Williams & Wilkins Company, 1941.

In this edition the material has been brought to date and the book has been considerably enlarged. The material on the vitamin B complex alone now covers about a hundred and fifty pages. There is included a section on vitamin K. The appendix includes descriptions of methods of studying the avitaminoses. There are tables of vitamin values of food. It should be a useful volume for those wishing a fairly concise statement of the chemistry and pathology of the vitamins.

**A History of Medical Psychology** By Gregory Zilboorg M D, in collaboration with George W Henry M D. Cloth Price, \$5. Pp 666 with 21 illustrations. New York: W W Norton & Company, Inc, 1941.

There have been many histories of neurology and psychiatry but few with the scope of this volume. Indeed, its more than six hundred pages and its somewhat involved approach to the subject make it primarily a work of reference for those especially interested in the field rather than for the general reader. Obviously, of greatest importance is the evaluation of the Freudian technic and the author's plea for tolerance in relation to new discoveries in this field. The volume is supplemented by a brief consideration of organic mental diseases by Dr George W Henry.

**Principles and Practice of Biological Assay** By James M Dill, Ph D, Department of Pharmacology, College of Pharmacy, University of Washington, Seattle. Third revision. Paper Price, \$1.75. Pp 100 with illustrations. Seattle: University of Washington, 1940.

In this mimeographed manual designed for student use, are provided instructions for the assay of cardiac stimulants, cardiac depressants, epinephrine, ergot preparations, posterior pituitary, insulin, local anesthetics, autonomic drugs, opiate, central nervous system stimulants and vitamins. The appendix provides some information on the methods for the determination of blood sugar and the examination of tissues for fat.

**Photometric Clinical Chemistry** By William S Hoffman Ph D, Professor of Physiological Chemistry, The Chicago Medical School, Chicago. Cloth Price \$3. Pp 254 with 27 illustrations. New York: William Morrow & Company, 1941.

This book provides a description of blood chemical determinations with the use of the Cenco-Sheard Sanford spectrophotometer. It should be of value to those who use this instrument.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### SEA WATER ENEMAS

To the Editor—I have been told that a person's fluid balance can be maintained by retention enemas of sea water. Could you furnish references or opinions on this subject?

Richard F. Holford, M.D., Fort McPherson, Co.  
First Lieutenant, M.C., U.S. Army

ANSWER—The salt content of sea water varies somewhat with the area from which it is taken, especially in relation to parts of the ocean near the entrance points of large rivers, but it is a distinctly hypertonic solution approximating a 3 per cent saline solution. From present knowledge of osmosis one would deduce that if sea water was introduced into the rectum and colon it would be abstracted from the body in states of health and dehydration. In the *British Medical Journal* (1 220 [Feb 16] 1918) Mr. Morley Roberts gave a view on the subject held by him since 1910, namely that sea water given by rectum might give up water to the body. His ideas were unsubstantiated by either experimental or personal observations, and his reasoning is untenable in the light of present day knowledge. However, he buttressed his contention by a recital of the personal experience of a Mr. R. Graham during a transatlantic voyage in 1916. The history of Mr. Graham's fast supplemented by rectal instillation of sea water is given without detail and of course without control. In *Surgical Treatment*, by J. P. Warbasse (Philadelphia and London, W. B. Saunders Company, vol. III, p. 58) this reference is cited and the ideas are restated without further proof of the soundness of the facts. In order to test this theory the following experiment was carried out. A healthy man aged 26 began a total fast and was kept under constant conditions of temperature and humidity. On the second day he experienced mild thirst and much hunger. The urinary output was 440 cc. On the third day there were severe thirst and dryness of the throat and the output of urine was 325 cc. in twenty-four hours. The nonprotein nitrogen level was 46.9. At noon slow proctoclysis of 1,000 cc. (1,024 Gm.) of artificial sea water was given. Within thirty minutes he complained of abdominal cramps. Infusion was stopped, and he expelled 346 Gm. of liquid material. There remained in the enema can 694 Gm. of fluid. (Part of this was reflux from the rectum.) At 3 p.m. the subject was more comfortable, and a second attempt was made with him in the knee-chest position, 250 cc. (266 Gm.) of sea water being instilled slowly into the rectum. Within fifteen minutes the subject had cramping abdominal pain and expelled 266 Gm. of liquid material containing a small amount of solid feces. Thirst continued and became worse. Analysis of the fluid expelled from the rectum showed it to be more dilute than that injected. The experiment was concluded by the subject and the conclusion derived from it was that there was no selective absorption of water from sea water administered by rectum to a subject in a moderate state of true dehydration produced by fasting and abstinence from water. This conclusion bears out current views on the diffusion of fluids and electrolytes through a permeable membrane.

### HEALTH HAZARD FROM TRINITROTOLUENE

To the Editor—I have had a number of inquiries from my patients regarding the likelihood of any injury, temporary or permanent, because of their contact with trinitrotoluene while working at the munition plant. Could you enlighten me on the subject? Edwin R. Talbot, M.D., Joliet, Ill.

ANSWER—Trinitrotoluene or TNT, is a high explosive with definite toxic properties. Workers in contact with trinitrotoluene may be poisoned if conditions are favorable for the absorption of this substance through the skin or through the respiratory passages. Dermatitis is not infrequent but usually is not especially severe. Mild poisoning produces such symptoms as headache, gastric disturbances, nausea and cyanosis. Blood changes, especially red cell abnormalities and anemia, are said to be the most reliable indication of incipient poisoning. Toxic jaundice and more rarely aplastic anemia were responsible for many deaths among trinitrotoluene workers in the first world war.

Persons who have a history of liver disease, anemia, bronchitis or asthma should not as a rule be allowed to work where

there is exposure to trinitrotoluene. It is most important that trinitrotoluene workers avoid alcohol.

Sometimes the damage to the liver does not show up for several months after exposure has ceased, but as a rule there is no permanent injury to health which does not become apparent during or shortly after the exposure.

The majority of large munitions plants in this country are aware of the health hazard from trinitrotoluene and are controlling it by preventing the absorption of excessive amounts and by frequent medical examinations of employees. The probability of workers in such plants becoming seriously poisoned by trinitrotoluene is not great.

Another explosive which is frequently handled in munitions plants is trinitrophenylmethylnitramine, commonly called tetryl. It is not believed that this substance causes systemic poisoning, but it is extremely irritating to the skin and workers with it frequently suffer a high incidence of dermatitis.

Further information on this subject can be obtained from the Division of Industrial Hygiene of the U. S. Public Health Service.

### USE OF NEGRO BLOOD FOR BLOOD BANKS

To the Editor—I have observed recently considerable agitation about the alleged discrimination against Negroes with regard to the use of their blood for the so-called blood banks for war purposes. Is there any definite basis in serology, pathology or hematology for the aversion to the use of their blood? Is the greater incidence of syphilis in the Negro race a factor in this aversion? Is present knowledge sufficiently complete with reference to all the blood elements for one to be able to say without contradiction that the use of Negro blood for blood banks is 100 per cent safe? S. Robert Thou, M.D., Brooklyn.

ANSWER—Numerous chemical and serologic investigations have yielded no evidence that the blood of one race can be distinguished from that of another. Manosloff (*München med. Wchschr.* 72 2186 [Dec. 18] 1925), a Russian investigator, devised for the differentiation of races a chemical test of the blood based on oxidation reactions, color changes in dyes serving as indicators. He and his colleagues claimed that they were able to distinguish by this method the blood of Russians, Jews and Ukrainians, but subsequent investigations by other workers have failed to substantiate their conclusions. The test was not applied to distinguish Negroes and Caucasians. This particular problem has been investigated chiefly by immunologists. Bruck (*Berl. klin. Wchschr.* 44 793, 1907) stated that by means of complement fixation tests he could distinguish the serum of a Caucasian, a Negro, a Malayan, a Chinese and an Arab. His experiments were repeated by many investigators, especially Marshall and Teague (*Philippine J. Sc.* 3 357, 1908), Fitzgerald (*J. M. Research* 21 41, 1909) and Landsteiner and Miller (*J. Exper. Med.* 42 841 [Dec.] 1925), none of whom could corroborate his data. Using the serum of a Caucasian, a Negro, a Japanese, a Negro and a Tagalog as antigens for comparison, Marshall and Teague could find no difference among them. Fitzgerald, in similar experiments, used the serum of a Caucasian, a Japanese and a Negro and obtained results that led him to say that "the existence of specific (serologic) differences has not been proven." Landsteiner and Miller, on repetition of Bruck's experiments, stated that if serologic differences exist between Negroes and white persons they are much smaller than those between man and the anthropoid apes. The significance of this statement is shown by the difficulty experienced by Nuttall in distinguishing between the primates and man by means of the precipitin test. In a review Landsteiner wrote that the only serologic peculiarities observed are those concerning isohemagglutinins and that these are not such as to demonstrate the existence of slight but regular differences by which the race of an individual could be ascertained but have only statistical significance and deal with the frequency of certain properties. In this respect these serologic qualities are comparable to more or less distinguishing but not always constant attributes of a race like the color of the eyes or hair or body weight. Wiener (*Blood Groups and Blood Transfusion*, Springfield, Ill., Charles C. Thomas, 1938) reached a similar conclusion as to the general failure to disclose race specific antigens. He stated: "Attempts have also been made to produce sera which would serve to differentiate the blood of different races of the human species. Thus far all attempts have failed." There is therefore no factual basis for the discrimina-

tion against the use of Negro blood or plasma for injection into white people. Since syphilitic blood is eliminated from use for this purpose by thorough serologic testing, the rate of syphilis in Negroes is of no concern in this connection. The transfusion of Negro blood into white persons and that of white persons into Negroes has been repeatedly performed in civil practice without any evidence of harm or aversion on the part of the recipients. The present agitation arises from the inopportune publication of orders prohibiting the inclusion of Negro plasma in the proposed military plasma bank. The aversion perhaps represents the persistence of the ancient folklore that one's personality is closely associated with one's blood. Frequently used clichés, such as "noble blood," are remnants remaining in the language from a day when such superstitions were more prevalent than they now are. Blood transfusions were originally practiced with the blood of stockyard animals. This practice was discontinued, not because of an aversion to the source of the blood, but because of severe and frequently fatal intravascular reactions. Patients repeatedly receive into the veins serum from rabbits, horses, sheep and other lower animals. These substances are received with an equanimity that is completely inconsistent with the aversion often associated with the injection of blood as much like that of the recipient as two substances can be.

#### A VAT FOR CADAVERS

*To the Editor*—I am having considerable difficulty keeping a cadaver preserved, since I have been unable to get a vat which is leakproof. I lined one with sheet metal and painted this sheet metal with Kodacoat on the advice of the Eastman Kodak Company. I was informed that Kodacoat is capable of withstanding chemical action of all kinds, but I found that this is an error. The Kodacoat lasted only a short time, and the metal beneath was shortly attacked and as a consequence my solution is blackened and ultimately I shall lose it. What is the best and cheapest method of making a vat?

M D, Texas

*ANSWER*—About the only material, apart from porcelain or glass lined metals, that will withstand corrosion by embalming or preserving fluids for cadavers is monel metal with the joints welded or soldered with hard solder. If a tank made of heavy sheet monel is strengthened by outer iron braces riveted to the sides, the rivets must be monel also, since galvanized iron or even heavy tin will eventually scratch through and rust.

The embalming fluid, however, should contain no formaldehyde or the cadaver may turn green (copper and nickel salt). The most satisfactory embalming fluid consists of equal parts of phenol (crystals), glycerin and denatured (without formaldehyde) ethyl alcohol.

Three to 5 per cent (crystals) in tap water is satisfactory as a preserving fluid. This solution will gradually darken but need not be renewed oftener than once a year, provided the monel cover fits fairly well.

#### BLOOD ALCOHOL DETERMINATION OF DRUNKENNESS

*To the Editor*—I should appreciate some information regarding findings in blood alcohol determination. What would be considered the line of demarcation between sobriety and drunkenness? Could a finding of 10 to 15 mg per cubic centimeter (0.10 to 0.15 per cent) be so considered? Would a finding of 3.25 mg per cubic centimeter (0.325 per cent) in the blood be considered as "very drunk"? Since alcohol produces stimulation and then depression, would you consider one who remains in an excitable state, with his memory still functioning after a five hour bout of drinking and able to attack ten armed men with his bare fists, as being under the influence of drugs, such as cocaine or marijuana, along with the alcohol?

Albert V. Anderson, M.D., Fort Devens, Mass

Captain, M. C., U. S. Army

*ANSWER*—There is no distinct line of demarcation between sobriety and drunkenness. However, there is a broad band of alcoholic percentage below which demonstrable alcoholic influence is unlikely and above which such influence is universal.

The American Medical Association Committee for the Study of problems of Motor Vehicle Accidents has recommended the following interpretation of the results of chemical tests for alcohol:

1. Although there is no minimal figure which can be set at which there will be absolutely no effect from alcohol, the committee recommends that persons with a concentration of alcohol of less than 0.05 per cent by weight in blood or its equivalent in urine, saliva or breath should not be prosecuted for driving while under the influence of alcoholic liquor.

2. All persons show a definite loss of that clearness of intellect and control of themselves which they would ordinarily possess when the concentrations are above 0.15 per cent in the blood or its equivalent in other body fluids or breath and should therefore be considered as under the influence.

3. When the alcohol concentrations are between 0.05 and 0.15 per cent in the blood, a great many persons will be under the influence of alcohol, but the committee recommends prosecution only when the circumstances and results of physical examination give definite confirmation of such influence.

An individual harboring 0.325 per cent of alcohol is unquestionably and definitely under the influence, although he may be able to coordinate well enough to engage an enemy vastly superior in numbers and equipment. The attack might be all the more effective because of the apparent sobering effect due to the increased secretion of epinephrine during the excitement. However, there can be no doubt that the aggressor's judgment is decidedly faulty in accepting such odds.

It is true that other drugs, particularly marijuana, might contribute to the man's recklessness, but the alcohol alone could account for his "courage."

#### TUMOR OF THE EYELID

*To the Editor*—A Negro woman aged 19 with a positive Wassermann reaction has an enlargement about the size of an almond kernel in the inner half of the right upper eyelid. This tumor-like structure is soft, and on one's placing a finger tip on it a thrill, synchronous with the pulse, is distinctly noted, in fact, the thrill is so pronounced that it suggests a sensation that might be produced by an electric current. The enlargement has not increased in size within the last several months, and it does not occasion any more discomfort or inconvenience than would arise from partial ptosis. The condition appears to be an arteriovenous aneurysm, but the vessels of the lids are normally so small that I am wondering if this is possible.

S. J. Lewis, M.D., Augusta, Ga.

*ANSWER*—If the enlargement mentioned is confined to the lid and has no visibly enlarged vessels leading into it on the skin or conjunctival side it is most unlikely that it is an aneurysm. It seems most likely that it is a chalazion. Such granulomas are common in the Negro race and reach a large size. The thrill synchronous with the pulse is probably transmitted through the lid from the globe, and the nodule may amplify the feeling of thrill. It should be possible to feel the thrill when placing the finger on the globe through the lid at some distance from the nodule, as pulsation of the globe with the pulse is not very rare and is due to pulsation of vessels in the orbit. It is possible that the nodule is a syphilitic granuloma, but these growths are rare in the lid. If it is a chalazion it should show a slightly lighter area on the tarsal surface along a meibomian gland. Incision and curettage of the nodule through the conjunctiva should completely remove the swelling if it is a chalazion.

#### ALCOHOL PACKS FOR INFECTED WOUNDS

*To the Editor*—What is the difference in effect on living tissue of ethyl alcohol and isopropyl alcohol? I am using Ochsner's solution of a diluted solution of alcohol and boric acid as a moist pack in treating infections. Can I use isopropyl alcohol, for instance in the form of Mifflin's Bathing Compound, interchangeably with grain alcohol in these solutions for moist packs on open wounds?

M.D., Minnesota

*ANSWER*—The use of ethyl alcohol in wounds is a procedure of doubtful wisdom. The stronger solutions which are bactericidal are painful and injurious, the weaker solutions (Ochsner's solution contains about 30 per cent ethyl alcohol) have little or no germicidal action in wounds, yet they may be capable of precipitating tissue proteins, stimulating inflammatory reaction and delaying the process of repair.

Propyl alcohol is equally objectionable. In vitro and on skin it possesses somewhat greater antibacterial power than analogous solutions of ethyl alcohol, but it is not known whether this is so in infected wounds also. Theoretically, the very qualities on which the superiority of propyl alcohol depends—ability to precipitate proteins, fat solvency and low surface tension—render it the more harmful to the tissues of wounds.

Neither ethyl nor propyl alcohol, used in the form of moist packs, approaches the ideal in the treatment of infected wounds which is to eliminate the infectious micro-organisms with injury to the tissues or retardation of healing.

#### POSSIBLE DEATH FROM "ETHER CONVULSIONS"

*To the Editor*—In Queries and Minor Notes in The Journal, March 14, 1947, appeared a letter regarding ether convulsions. I noticed that in the answer it stated there was no specific treatment for this condition. On more than one occasion I have seen Dr. John Lundy, the head of the department of anesthesia in the Mayo Clinic, meet just such a situation with the intravenous use of pentothal sodium, which promptly relieves the convulsions. In each instance, the patient went on to an unremarkable recovery. I thought this might be of some interest in view of the fact that, although ether convulsions are not common, they are of a serious nature uncommon as is seemingly appreciated.

## THE ORIGIN OF CANCER IN MAN

WILLIAM CRAMER, M.R.C.S., D.Sc., Ph.D.  
ST. LOUIS

The title of my paper might be expressed more simply by the question "Why does a patient get cancer?" This is a question which must have come often to your mind. If a patient presents himself or herself at an early stage of the disease when the growth is still small, the feeling or the seeing of a tumor may have been the very first sign of the disease. There may be no other symptoms, not even pain, the patient is apparently in good health, there is no previous history of any disease or trauma; the disease appears like a "bolt from the blue."

The early workers in cancer research laboratories had the same experience. They kept large numbers of young mice or of rats together in big cages on the same diet. After a while one of these animals, which had never been subjected to any experimental procedure, would suddenly develop a malignant growth; then in a second and later perhaps in a third animal a tumor would appear, while the bulk of the animals, though kept under identical conditions in the same cage and on the same food, would complete the natural span of their lives free from cancer. It was thus taken for granted that cancer arises suddenly in a previously normal tissue, and it was this sudden, unexpected and apparently capricious appearance of the disease which gave to it the aspect of a grim mystery. It also gave rise to the conception that the origin of cancer was to be found at the time of the first appearance of a malignant cell.

The attention of students of cancer thus became riveted on the investigation of the nature of the malignant cell as the one and only problem in the etiology of cancer, which became limited to an explanation of the unrestricted growth of the cancer cell. Since it was proved conclusively by the early work on the transplantation of spontaneous tumors in animals that this unrestricted growth was due to a change lying entirely within the cell and was not brought about by growth stimuli acting on the cancer cell from without, the solution of the cancer problem seemed to be confined to an explanation of this intracellular change. And since it seemed justifiable to assume that this intracellular change is the same in whatever tissue or organ it occurs, cancer appeared to be, from the etiologic

point of view, a single disease and the nature of this intracellular change was spoken of as "the cause of cancer." Various lines of attack on the nature of this intracellular change have been followed, but this problem still awaits a solution. What has completely changed the aspect of the cancer problem and opened up new ways and means of attacking it is the recognition that cancer does not arrive suddenly and that the intracellular change represents only one aspect of a very complex problem.

One of the characteristic features of the disease is its age incidence: cancer increases rapidly in almost geometrical progression as age advances. This was explained formerly by the assumption that senile tissues are particularly prone to the cancerous change. When it became possible to produce cancer experimentally, by a variety of carcinogenic agents, it was found that cancer can be induced as readily in a young organism as in an old one. The senility of an organism does not, therefore, account adequately for the characteristic age incidence of the disease. The explanation must be sought elsewhere. It lies in the fact that the intracellular change represents the culmination of a process which occupies a long period of time. This period—the period of induction—is not the same for different species of animals if expressed in units of astronomical time. But there is a striking similarity if we express the results in units of biologic time, that is to say, in equal fractions of the natural life span of each species. The production of cancer by coal tar requires on the average six months in a mouse and fifteen years in man. With a life span of two years for a mouse and seventy years for man, six mouse months represent one fourth of the life span of a mouse and fifteen human years nearly one fourth of the life span of man. During this long period of induction the tissue on which the carcinogen acts undergoes a series of pathologic changes involving among other things increased cell division. Eventually this altered tissue passes into a condition in which a few cells within this altered tissue undergo, sooner or later, an irreversible intracellular change which transforms them into malignant cells. When this happens the scene changes from the exterior to the interior of the cell.

## THE ORIGIN OF CANCER: PROXIMATE AND REMOTE CAUSES OF CANCER

The irreversible intracellular change, when it has once occurred, persists within the cell even after the carcinogenic agent has been withdrawn. The recent work on experimental carcinogenesis has thus in no way changed the fundamental conception that the autonomous infiltrative growth of the cancer cell is a property residing within the cell. On the contrary, it has confirmed and extended it. But it has made

From the Barnard Free Skin and Cancer Hospital.  
Read before the St. Louis Medical Society, March 3, 1942, on the occasion of the presentation to Prof. Leo Loeb of the Award of Merit and the Gold Medal of the Society.

Dr. Cramer is research associate, the Barnard Free Skin and Cancer Hospital, St. Louis, and late senior member of the Research Staff, Imperial Cancer Research Fund, London, England.

it clear that the expression "the cause of cancer," which was used previously, has become meaningless. As far as the birth of a new race of cells—the cancer cells—has its immediate origin in an intracellular change, this change may be called the proximate cause of cancer. But since this change occurs most frequently—if not always—in a tissue which has undergone pathologic changes as the result of having been exposed to the action of a carcinogenic agent, we must take account of this more remote origin of cancer by distinguishing the "remote causes" of cancer from the "proximate cause" or causes. Eventually, when more is known about the nature of the intracellular change, we may be able to understand the connection between these two problems. At present they have to be treated as two separate and distinct problems requiring a different technical approach and involving different biologic conceptions. The experimental study of the remote causes of cancer has made it possible to interpret a number of hitherto obscure features concerning the origin of cancer in man and to open up ways and means by which this problem can be attacked in the human subject. Since the etiology of cancer involves a consideration of a plurality of remote causes, the term "remote causal factors" seems preferable. These may be conveniently divided into four groups, which will now be discussed briefly. They are

- 1 Carcinogenic agents
- 2 The precancerous condition
- 3 Susceptibility
- 4 The time factor

#### CARCINOGENIC AGENTS

The carcinogenic agents which have so far been identified differ greatly in their nature. They may be chemical substances, physical agents such as roentgen rays, radium rays or ultraviolet light rays, or gross parasites such as *Taenia crassicolis* in rats, *Bilharzia* in man. The chemical substances, of which about one hundred and seventy have been identified, fall into two groups: (1) substances foreign to the physiologic economy of the body and not formed by it normally and (2) substances normally formed by the body and possessing definite physiologic functions. Examples of the first group are tar, dibenzanthracene, benzpyrene and methylcholanthrene. These different chemical substances, which have a mildly toxic effect on the animal organism, vary greatly in their carcinogenic potency. They are locally carcinogenic for the skin when applied to it. When injected subcutaneously they are also locally carcinogenic for connective tissue. They also produce cancer locally at the site of their application in a number of internal organs, including the stomach, intestine and mamma. They may also produce cancer remotely in the lungs, either when applied to the skin or when injected subcutaneously. To this group belong also a number of organic dyestuffs, such as butter yellow, which when ingested with the food are specifically carcinogenic for one organ, the liver, but not for other organs. The fact that some of the chemical substances known to induce skin cancer in man, such as tar, shale oil and radiations, also induce skin cancer in mice and other species of animals is evidence of the essential similarity of the experimental disease to the disease as seen in man. Although a large number of chemical carcinogens have been synthesized, their mode of action is still obscure. A systematic investigation organized by Dr. E. V. Cowdry is now under way in the Barnard Hospital in St. Louis. One result obtained so far

which has a bearing on the etiology of cancer in man is that the exposure of a tissue to the carcinogenic agent need not necessarily be long continued and unremittent, as has been generally assumed. A few isolated exposures to a powerful carcinogenic agent, separated from one another by long intervals of time, can be effectively carcinogenic.<sup>1</sup> Under special conditions even a single exposure of the skin to a chemical carcinogen is sufficient so to alter the epithelium as to send it on its way to the development of cancer.

In contrast to this group is the group of carcinogenic hormones, such as the estrogens. They are formed in the body and fulfil definite physiologic function. They may be either the actual hormones normally present or organic substances having a different chemical constitution but possessing the same physiologic properties. This means that their carcinogenic effect is tied up with their physiologic action. They are specifically carcinogenic for a group of organs not exposed to agencies coming from without but influenced physiologically by these hormones, organs such as the mamma, the uterus, the prostate and the thymus. They are not carcinogenic for the skin.

Quite recently a number of facts have come to light which indicate that there is a fundamental difference in the mode of action of the chemical carcinogens on the skin and that of the estrogenic hormones on the mamma. The former, which, as already stated are foreign to the physiologic economy of the body and have a mildly toxic effect on the organism, induce at their first application an injury to the cells of the skin followed by an excessive regeneration. The resultant epithelial hyperplasia is, therefore, an indirect effect. The estrogenic substances, on the other hand, induce a hyperplasia of the mammary epithelium as a normal response of a tissue to its physiologic chemical stimulus. The subsequent development of cancer in the mamma is dependent on the presence of a substance of a high molecular weight, the exact nature of which has not yet been identified. This substance is transmitted from its mother to the individual animal immediately after birth in the milk. This is the so-called "milk factor" of Bittner.<sup>2</sup> This milk factor is stated to be present only in strains with a high incidence of spontaneous mamma cancer, it is absent in strains with a low incidence.

While the presence of this milk factor is essential for the induction of cancer in the mamma by estrogenic substances, cancer can be made to develop in that organ in the absence of the milk factor if a chemical carcinogen such as methylcholanthrene is locally applied to the mammary gland. For Strong<sup>3</sup> has shown that by this technic cancer can be induced in the mamma of mice belonging to a strain in which breast cancer never develops spontaneously in the females and cannot be induced experimentally in the males by estrogen. Ex hypothesi, the milk factor is absent in such a strain. It follows from this that the origin of cancer in the mamma and the same organ, the mamma, can be due to widely varying combinations of remote causal factors. But one fact stands out, whatever the combination of remote causal factors may be and whatever the time has to elapse before the action of these factors

- 1 Cramer, William, and Stowell, R. E. *Cancer Research* 1: 155, 1941.
- 2 Bittner, J. J. *Am. J. Cancer* 36: 44, 1939; *J. Nat. Cancer Inst.* 1: 155, 1940.
- 3 Strong, L. C. and Williams, W. L. *Cancer Research* 1: 155, 1941.

on a given tissue culminates in the development of cancer. What occurs during that period? This leads directly to a consideration of the second item on our list.

#### THE PRECANCEROUS CONDITION

During the prolonged period of induction necessary for a carcinogenic agent to elicit cancer, the tissue on which these agents act undergoes a pathologic change and it is in this altered tissue that eventually a malignant condition develops in a sharply circumscribed area. In the two tissues in which experimental carcinogenesis has been studied most extensively—the skin and the mamma—this alteration consists as far as the epithelium is concerned, in hyperplasia, which in the skin becomes visible to the naked eye frequently though not always, in the form of papillomas. But it must not be assumed from this that every form of hyperplasia is a precancerous condition or that a papilloma must necessarily develop into a carcinoma. There are, as we shall see, in man certain atrophic conditions of the epithelium which have been recognized as precancerous. The significance of the precancerous condition will be discussed again later.

#### THE HOST FACTOR OF SUSCEPTIBILITY

When carcinogenic agents are applied to the skin of animals they do not produce their carcinogenic effect uniformly, in some animals cancer appears earlier than in others, and in some individuals cancer does not appear at all. These differences become even more well defined when estrogenic hormones, which are carcinogenic for the mamma, are applied to inbred strains differing in their spontaneous incidence of mammary cancer. The ovarian follicular hormone, which may produce 100 per cent of mammary cancer in the males of one particular strain with a high incidence of spontaneous mamma cancer in the females, may produce no carcinogenic effect at all in the males of another strain in which cancer never develops spontaneously in the mamma. There is, therefore, a factor residing in the host and transmitted to it from its parents which determines the efficacy of a carcinogenic agent. This factor is designated by the intentionally vague term susceptibility. By applying the methods of genetics<sup>4</sup> to the cancer problem it has been demonstrated among other facts that the factor of susceptibility does not extend to all organs of an individual but is restricted to one particular organ. Thus it is possible to produce by inbreeding a strain of mice with a very high incidence of spontaneous cancer of the mamma, indicating a high degree of susceptibility to cancer in the mamma. But the skin of the animals belonging to such a strain is not necessarily more susceptible to the carcinogenic action of a chemical carcinogen.

The relationship between the two factors susceptibility and carcinogenic agent can be expressed crudely by a simple equation of two variables,  $A$  and  $S$ , and a constant,  $C$

$$A \times S = C$$

In such an equation the one variable increases as the other diminishes. If  $A$  represents the carcinogenic agent,  $S$  the susceptibility and the constant  $C$  the carcinogenic effect, the equation expresses the fact that cancer can arise in an organism either with a high susceptibility and a weak carcinogenic stimulus or with a low susceptibility and a strong carcinogenic stimulus. The equation reads therefore

$$\text{Carcinogenic Agent} \times \text{Susceptibility} = \text{Carcinogenic Effect}$$

<sup>4</sup> Little C. C. A Review of Progress in the Study of the Genetics of Spontaneous Tumor Incidence. *J Nat Cancer Inst* 1: 72-1941

#### THE TIME FACTOR

There is yet a third variable which enters into the etiology of cancer, the factor of time. A considerable period of time is necessary for a carcinogenic agent to induce cancer even in a susceptible animal, and this prolonged period varies inversely with the strength of the carcinogenic stimulus and with the degree of susceptibility. It is shortest when a strong stimulus is applied to a highly susceptible animal, and it is very long when the two other variable factors have low values. This can be expressed by the equation

$$\text{Time (Carcinogenic Agent} \times \text{Susceptibility)} = \text{Carcinogenic Effect}$$

This means that the appearance of cancer at an early age indicates a strong carcinogenic stimulus or a high degree of susceptibility or a combination of the two. If, on the contrary, the carcinogenic stimulus has been weak or intermittent or/and if the degree of susceptibility has not been high, cancer will develop at later age periods. The longer the individual lives, the greater is the chance that a product of carcinogenic stimulus and susceptibility too weak to elicit cancer in early middle age will become effectively carcinogenic. This accounts for the rapid increase in the cancer incidence rate with advancing age.

#### THE ETIOLOGY OF CANCER IN MAN. CANCER A MULTIPLICITY OF DISEASES

Cancer in man may be considered as an experiment carried out by nature on the human species. But in this case we see only the end results of the experiment. In order to trace the various factors which have taken part in this experiment we must adopt a "follow-down system." The follow-up system, with which we are all familiar, enables us to determine the results of treatment. It tells us nothing about the origin of the disease. The follow-down system is only now beginning to be developed. It attempts to trace the disease in man back to its origins in the light of the knowledge gained from the experimental analysis of the disease in animals.

The first thing to bear in mind in such investigations is the great variety and variability of the etiologic factors. They are different for different organs, and even for one and the same organ there may be a variety of ways in which the several factors are present in combination. We must recognize that from the point of view of the remote causes cancer is a multiplicity of diseases in man as it is in animals. In order to trace the various etiologic factors, the vast bulk of data concerning human cancer has to be broken down into separate groups. I shall try to illustrate this point by discussing briefly the following groups:

- Primary liver cancer
- Hereditary factors
- Social factors
- Precancerous conditions
- Gastric cancer
- The hormonal etiology of breast cancer

#### PRIMARY CANCER OF THE LIVER

This disease is very rare in Europe and in this country. It is often found in the natives of the Far East and of South Africa,<sup>5</sup> and, where accurate statistical observations have been available, it has been found that the liver is the organ most frequently affected by cancer. This difference has until recently been a remarkable and puzzling phenomenon. Here is the explanation.

<sup>5</sup> The literature is reviewed by Shear M. J. *Am J Cancer* 29: 269, 1937.

Japanese investigators<sup>6</sup> found that primary liver cancer could be induced in mice and rats by adding certain azo dyes, such as butter yellow, to the diet. Such dyes are used in the artificial coloring of foodstuffs. When the experiments were repeated in European and American laboratories, liver cancer did not develop as readily or failed to appear altogether. Further investigation showed that this discrepancy was accounted for by the fact that the stock diet of the animals in Japan consisted of rice and carrots, while in European and American laboratories the stock diet was more varied and built around wheaten cereals as the basic foodstuff. This difference reflects of course general differences

TABLE 1—Proportionate Cancer Mortality in Sibs of Basal Patients with Cancer, Analyzed by Organs (Waalder)

| Percentage Incidence of Cancer in General Population |    | Lip |    | Other Sites |    |    |    | Stomach, Liver, Esophagus |    |    |    | Uterus, Breast and Ovaries |    |    |   | Prostate |   |

BP = basal patient

in the respective diets consumed by different races of man in different parts of the world. Further experimental analysis by Rhoads and his collaborators<sup>7</sup> demonstrated that the two dietetic factors responsible for the difference were casein and a vitamin—riboflavin—belonging to the B complex. When these two substances are added to a diet of rice and carrots, butter yellow does not induce liver cancer.

In the story of cancer research this recent analysis of the etiology of liver cancer is one of the most interesting chapters and it is worth while to consider it in some detail. We have here again two remote causes—a carcinogenic agent—butter yellow—and the susceptibility of the liver to that agent. But in this case the susceptibility factor is not inherited or transmitted from the parent but is dependent on conditions acting on the organism from without—namely the diet. We have here also a striking demonstration of the close similarity existing between the etiologic factors determining the development of cancer in man and in animals. It is true that we have not yet identified the carcinogenic agent responsible for the prevalence of primary liver cancer among the natives of the Far East, but the dietary factor predisposing the liver, and only the liver, to the development of cancer is the same for rats and for human beings. It is therefore justifiable to conclude that liver cancer, as it occurs among the natives of the Far East, can be prevented by dietetic measures.

FAMILIAL INCIDENCE OF CANCER IN MAN

When this subject was first studied, the total incidence of cancer of all organs was made the basis of all investigations. For reasons which will become evident, such investigations failed to reveal any pronounced differences of the cancer incidence between persons with and persons without a family history of cancer.

In two more recent investigations carried out independently by Wassink<sup>8</sup> in Amsterdam and by Waaler<sup>9</sup>

in Norway the material collected by them was further analyzed according to the organ incidence. Since these two investigations are not readily accessible they will be discussed in some detail.

The basis of the material used for such investigation were persons known to suffer or to have suffered from cancer of the various organs. These are called the "basal patients." The next step was to collect information about the incidence of cancer in the near relatives of the basal patients—either the brothers and sisters—"sibs" for short—or brothers, sisters, parents, aunts and uncles. It thus became possible to determine first whether the near relatives of persons with cancer of the one organ develop cancer more frequently than does the rest of the population (table 1).

The figures show that the sibs of male basal patients with lip cancer do not suffer from cancer more frequently than the general population. There is a definite increase for the sibs of basal patients with cancer of the esophagus and stomach, and in this group there is a definite sex difference, the brothers of female patients with cancer of the esophagus or stomach showing the lowest frequency in this group. A remarkably high incidence is found among the sisters of basal female patients with cancer of the female sex organs but not among the brothers, and among the brothers of basal male patients with cancer of the prostate but not among the sisters. A second important finding was that in this population of sibs, cancer developed at a much earlier age (table 2).

The next step was to see whether the organ incidence in the cancerous relatives of basal patients suffering from cancer of one particular organ, e.g. the mamma, was the same as it is in the general population, which would indicate a general susceptibility to cancer of all organs, or whether it was different from that of the general population. Waaler found that in cancer of the mamma an inherited susceptibility affects mainly the female relatives (as seen in table 1) and in those female relatives mainly the "homotope organ"—the mamma (table 3).

TABLE 2—Proportionate Cancer Mortality in Sibs of Basal Patients with Cancer, Analyzed by Age Groups (Waalder)

|                    | Males in Age Groups |     |     |     |     | Females in Age Groups |     |     |     |     |
|--------------------|---------------------|-----|-----|-----|-----|-----------------------|-----|-----|-----|-----|
|                    | 40-                 | 50- | 60- | 70- | 80- | 40-                   | 50- | 60- | 70- | 80- |
| General population | 11                  | 20  | 22  | 14  | 5   | 16                    | 22  | 21  | 19  | 1   |
| Sibs               | 16                  | 42  | 27  | 18  | 5   | 49                    | 47  | 30  | 1   |     |

That is to say, among 100 cancerous women whose sister is afflicted with cancer of the breast—the breast patients—45 women would have cancer of the breast while in 100 cancerous women whose sisters—the breast patients—had cancer in some organ other than the mamma, only 16 women would have cancer of the breast. This proportion (16 per cent) of breast cancer in the total organ incidence approximates that found in the general female population.

A strikingly similar result was obtained by Waaler in the Netherlands (table 4).

This table is given here because it illustrates an important point, namely the chance of a development of cancer incurred by the close relatives of basal patients with breast cancer. This is a question frequently asked by relatives of cancer patients. In Wassink's study there are 660 women as basal patients with breast

6 Sasaki, T., and Yoshida, T. Virchows Arch f path Anat 295 175, 1935.  
7 Kensler, C. J., Sugiyura, K., Young, N. F., Halter, C. R., and Rhoads, C. P. Science 93 308, 1941. Sugiyura, K., and Rhoads, C. P. Cancer Research 1 3, 1941.  
8 Wassink, W. F. Genetica 17 103, 1935.  
9 Waaler, G. H. M. Ueber die Erblichkeit des Krebses, Norske Videnskaps Akademi Oslo, 1931.

cer Only 207 of these women had a history of cancer in other members of the family, so that as many as 453 of these basal patients had no relatives with cancer of any organ. But in the 207 basal patients with cancerous relatives the incidence in the relatives of breast cancer was remarkably high. Among the 192 cancerous female relatives more than one half had breast cancer, namely 112 women while in the general population of Dutch women breast cancer affects only about 10 per cent of all cancerous women.

These relationships, observed in the human subject, harmonize remarkably well with those arrived at from the experimental side. For sites such as the lip or the

chief medical officer to the registrar general of England, has demonstrated that this relationship extends far beyond the skin and beyond occupational cancer and applies also to the upper part of the alimentary tract. His analysis was carried out on the male population in England, which he divided into five social classes. Studying the cancer incidence for a number of separate organs he found that in the organs exposed to exogenous carcinogens which in addition to the skin include the alimentary tract from the mouth down to and including the stomach the cancer incidence was highest in the lowest social class and fell with a regular diminution through the other social classes to show the lowest incidence in the highest social class. In the group of organs not exposed to agencies coming from without, a group which includes the lower alimentary tract, the incidence of cancer was approximately equal in the different social classes. These results are important both from theoretical and from practical points of view. They show as a general proposition that the etiologic factors concerned in cancer of the upper alimentary tract are different from those operative for the lower alimentary tract. Their practical importance lies in the inference that the high incidence of cancer of the upper alimentary tract is related to the mode and habits of life of the lower social classes. This relationship may be called 'social cancer.' I have said earlier that cancer in man is an experiment carried out by nature on man. But occupational cancer is really an experiment carried out by man in his ignorance on himself. When the study of experimental carcinogenesis demonstrated the fact that in some occupations man exposed himself to chemical substances which were carcinogenic for the skin of animals, occupational cancer became a preventable disease. Social cancer is also an experiment carried out by man in his ignorance on himself, and with increasing knowledge of the exogenous factors involved it should, like occupational cancer, become a preventable disease.

We have here another example of the value of breaking up the available data concerning human cancer into

TABLE 4—Incidence of Cancer of All Organs and of Breast in Relatives of Patients with Breast Cancer (Hassink)

|   |             |
|---|-------------|
| Number of basal patients with breast cancer                 | 600 females |
| Number of these basal patients having relatives with cancer | 207 female  |
| Number of relatives with cancer of all organs               | 301         |
| Females   | 192         |
| Males   | 109         |
| Number of relatives with breast cancer                      | 112 females |
| Number of relatives with cancer of organs other than breast | 189         |
| Females   | 89          |
| Males   | 100         |

groups if we wish to obtain an insight into the remote causal factors determining the incidence of cancer in man. Previous investigations on the incidence of cancer in different social classes had failed to yield differences which statisticians considered to be significant. But when each site is considered separately a definite relationship comes to light.

Social cancer affords a clue to the nature of the etiologic factors for cancer of these sites. It even suggests the possibility of preventing the disease. If the mode and habits of life of the lower social classes could be corrected so as to bring them up to the standard of the higher classes it is justifiable to expect that a considerable diminution in the incidence of cancer of the upper alimentary tract would result.

TABLE 3—Percentage Cancer Incidence in Hamotopie and Heterotopie Organs in Sisters

skin sites exposed to agencies acting from without the incidence of cancer is predominantly determined by the absence or presence of a carcinogenic agent coming from without—the 'exogenous carcinogenic agents.' For organs not exposed to the same extent to agencies acting from without but subject to hormonal influences leading to carcinogenesis such as the mamma and the uterus—the 'endogenous carcinogens' as we may call them—the incidence of cancer is governed largely by intrinsic factors of susceptibility. For such organs as the esophagus and the stomach which are exposed to agencies coming from without the development of cancer depends on both factors—the presence of exogenous carcinogenic agents and the existence of an intrinsic inherited susceptibility of which either the one or the other may predominate.

We have just seen how the incidence of cancer is affected in a population selected in such a way that the intrinsic factor of susceptibility predominates. How can we go about to select a population in which the incidence of cancer is governed by the presence of exogenous carcinogenic agents? This brings us to the next section.

#### SOCIAL FACTORS IN CANCER

For organs exposed to carcinogenic agents coming from without 'exogenous carcinogens' the incidence of cancer is determined largely by the presence or absence of the exogenous carcinogens. This is clearly demonstrated by occupational cancers. Cancer of the scrotal skin is rare among the general population but relatively frequent among the chimney sweeps and among the cotton spinners in England who are exposed to the mineral oil used for lubricating the spindles the so-called 'mule spinners' cancer.' In these occupations the carcinogen induces scrotal cancer. It does so only in a fraction of the individuals exposed to the carcinogenic agent namely in those persons with a high susceptibility to skin cancer, but even these persons would not have developed scrotal cancer if they had not engaged in those particular occupations. The occupation determines the incidence. A statistical analysis carried out nearly twenty years ago by Stevenson,<sup>10</sup>

<sup>10</sup> Stevenson, T. H. C. Registrar General's Decennial Supplement England and Wales 1921 Part II London 1924.

This would apply also to the stomach. Cancer of the stomach is responsible in most European continental countries for one half or more of the total cancer mortality. In this country it can be estimated to kill on the average 150 persons every day of every year. It presents a problem which cannot be easily investigated in animals, because in almost all species of animals gastric cancer is very rare and it has been difficult up to now to induce it experimentally with any degree of regularity. For investigations on the etiologic factors we are, therefore, dependent at present mainly on clinical and pathologic observations on man. For such investigations the conception of the existence of precancerous conditions on the basis of which cancer develops has been particularly helpful. Before discussing the etiologic factors for cancer of the stomach in man, I shall have to consider briefly the general meaning of the precancerous condition.

#### PRECANCEROUS CONDITIONS IN MAN

Let me recall that, when a carcinogenic agent is allowed to act on a tissue, a considerable period of time elapses before the development of a malignant condition manifests itself. During the prolonged preparatory period the tissue undergoes a pathologic change.

The conception of a precancerous condition is not new. It was first formulated many years ago by dermatologists for certain pathologic skin conditions and it was then defined as a condition in which cancer arises subsequently with a high degree of frequency. For man that definition still holds good. In human cancer it is, necessarily, a purely empirical definition and is not based on morphologic criteria, as is cancer itself. It is easy to understand why it should have been formulated by dermatologists. For in the skin the whole process of carcinogenesis is visible to the naked eye. It was later recognized also for some other organs visible to inspection, such as the tongue or the vulva. But these examples were considered by many as pathologic curiosities and not as visible examples of a general phenomenon preceding cancer. In fact, such a generalization has been contested even in recent years—and sometimes contested with some heat—by writers who claimed to speak with authority on cancer. But since it has been demonstrated experimentally that carcinogens, to produce their effect, require a prolonged period of time during which the tissue on which they act undergoes a series of pathologic changes, and since, as explained previously, the characteristic age incidence of spontaneous cancer in man and in animals finds an explanation in this long period of induction, the existence of a precancerous condition has established itself as a fairly general phenomenon in the origin of cancer. It has encouraged clinicians and pathologists to search for such conditions in different organs.

It should be noted that the precancerous condition is not necessarily represented by an epithelial hyperplasia, as in experimental skin cancer. It may be an epithelial atrophy. There are quite a number of atrophic conditions which have been found empirically to be precancerous, such as radiation dermatitis, kraurosis vulvae and the atrophic undescended testicle. Whether an epithelial hyperplasia as such or an epithelial atrophy as such are precancerous depends on the conditions by which they were produced. In the gastric mucosa three precancerous conditions have been identified: one, a gastric polypus, is hyperplastic, the two others are atrophic in nature—a gastric ulcer and chronic atrophic gastritis.

#### THE ORIGIN OF CANCER OF THE STOMACH

The stomach is in man the organ most frequently affected by cancer. In this country about 30 per cent of the total recorded mortality from cancer is represented by the recorded mortality from gastric cancer. I intentionally use the expression "recorded mortality," because there is reason to believe that gastric cancer is grossly underdiagnosed and that the actual incidence of gastric cancer is much higher. I also use intentionally the terms "mortality from gastric cancer" and "incidence of gastric cancer" as synonymous in order to bring home the fact that the percentage of patients with gastric cancer that are cured by operation is depressingly low. Even in the best clinics it does not exceed from 3 to 5 per cent of all patients. These unsatisfactory results have engendered in the medical profession a pessimistic outlook on the disease. But in view of the outstanding frequency of this form of cancer it is clear that we cannot hope materially to diminish the total cancer mortality unless there is an improvement in the results of the treatment of gastric cancer, and there are now reasons for a less pessimistic outlook. In making this statement I do not presume to offer a personal opinion. I rely on statements made by men better qualified by personal experience to judge than I am. I refer particularly to the views expressed at the recent conference on gastric cancer organized by the National Advisory Council on Cancer in October 1940 and reported in the *Journal of the National Cancer Institute* in February 1941 and to the monograph by E. M. Livingston and G. T. Pack "End Results in the Treatment of Gastric Cancer," published in 1939.<sup>11</sup> Briefly summarized, the argument runs as follows: Gastric cancer can be cured in from 30 to 40 per cent of those cases which come to the surgeon at a stage when the disease is operable and before wide dissemination has occurred. This amounts at present to about 15 per cent of all cases of gastric cancer diagnosed as such. Gastric cancer is admittedly difficult to diagnose at this stage, and the low percentage of successful treatment is due mainly to the fact the great majority of patients—about 85 per cent—reach the surgeon at a stage at which the disease has become inoperable. On this point Livingston and Pack have this to say: "The medical practitioner, the consultant and the radiologist may play precisely as great a practical role as the expert surgeon through their influence on the most important single item, that of high operability rates." And again: "The operability rate among patients with gastric cancer may be looked upon as an index of medical efficiency in the management of the disease. The role of the medical practitioner equals or even exceeds the importance of the role of the skilled surgeon." One reason for a more hopeful outlook is the improvement in modern methods of diagnosis. A second reason is the possibility of recognizing the existence in patients of precancerous conditions. A third reason is the significance of a family history of gastric cancer. The question may be raised whether the recognition of a precancerous condition in the gastric mucosa of a person with a family history of gastric cancer should not justify immediate surgical intervention. Lastly there is the fact that carcinomas of the gastric mucosa vary greatly in their tendency to metastasize, so that some types of gastric carcinoma may reach a considerable size before they develop metastatic growths.

<sup>11</sup> See also Cooper, W. A. "The Problem of Gastric Cancer," *M. A.* 116: 2125 (May 10) 1941.

The importance of the pathologic conditions in the gastric mucosa which may lead to cancer raises the question of their etiology. A chronic atrophic gastritis, which is the condition most frequently preceding cancer, may be brought about by a variety of conditions. They can be summarized as chemical, mechanical or biologic insults to the gastric mucous membrane. An example of a biologic insult which may be an etiologic factor in gastric cancer is represented by defective oral hygiene or, in plain English, a "dirty mouth." This leads to defective mastication and to the continued swallowing of infected matter. These considerations rob the etiology of cancer of the stomach of the mystery which has been believed to surround it and they direct attention to factors which are so frequent and familiar that they might be called banal. It is probably this group of etiologic factors which is responsible for "social cancer," i. e. the higher incidence among the lower social classes of cancer of the upper alimentary tract. In most people these insults to the gastric mucous membrane will not go beyond an atrophic gastritis or possibly an ulcer, but in individuals with an inherited susceptibility to gastric cancer they eventually induce cancer. There is so far no convincing statistical evidence that the excessive consumption of alcohol is an important factor in inducing gastric cancer, but Wassink has brought evidence that it is of etiologic significance for the pharynx and esophagus.

#### A HORMONAL ETIOLOGY OF CANCER OF THE MAMMA AND OF SOME OTHER ORGANS

The discovery that cancer can be induced by a number of chemical substances foreign to the physiologic economy of the body—that is to say, substances not formed by the body—has made it possible to understand the development of cancer in man in such an organ as the skin, which is exposed to agents coming from without. But how does cancer arise in organs not so exposed? A hormonal etiology of cancer of the breast was first predicated by Leo Loeb<sup>12</sup> twenty-three years ago. It has been demonstrated experimentally for organs, such as the mamma, the uterus and the thymus that substances formed in the body and having hormonal functions may be carcinogenic for these organs. At first sight the fact that a hormone can induce cancer seems startling. But on consideration it solves a difficulty. That cancer can be induced in the exposed sites by the action of carcinogenic agents which play no part in the physiologic economy of the organism is easy to understand. The difficulty was to conceive how cancer can arise in organs and tissues not accessible to the action of such exogenous carcinogenic agents. The experimentally established fact that a substance formed in the body and circulating in the blood stream is carcinogenic for at least some of these unexposed organs, the mamma, the uterus, the prostate and the thymus, resolves this difficulty. But it raises at the same time a new problem. If a hormone can act as a carcinogen for a certain organ why does not cancer develop in every individual?

We know that the strength of the carcinogenic agent—in this case the estrogenic hormone—is one factor. Observations on different strains of mice give no evidence that the females of the high cancer strains secrete more estrogen than those of low cancer strains. But the estrogenic hormone of the ovary is functionally integrated with the hormones of the other endocrine

organs.<sup>13</sup> Some of these act synergistically, e. g. a hormone from the adrenal cortex, others antagonistically, e. g. a hormone from the anterior pituitary. As a result of this endocrine integration, alterations in the functional activity of some endocrine organs other than the ovary may lead to an endocrine imbalance either in the direction of reinforcing the action of the estrogen or in the opposite direction of antagonizing it. In the maintenance of this endocrine balance for the female sex hormone the pituitary gland and the adrenal glands take a leading part. Adrenalectomy makes the animals resistant to the effect of the estrogenic hormone.<sup>14</sup> Ovariectomy, if performed at birth, leads after a long time interval to a nodular hyperplasia of the adrenal cortex in strains of mice with a high incidence of spontaneous breast cancer but not in low cancer strains. The adrenocortical hyperplasia is followed by development of the mamma which may proceed to cancer.<sup>15</sup> A remarkable feature of this phenomenon is that it applies also to male animals, in which castration soon after birth may lead to a nodular hyperplasia of the adrenal cortex and even to mammary cancer.<sup>16</sup> It is conceivable, then, that a disturbance of the endocrine balance in a direction enhancing the functional activity of the estrogenic hormone such as an adrenal cortical adenoma, may be an etiologic factor for breast cancer. The association of such changes in the adrenals with spontaneous mammary cancer in animals has been recorded by Bagg<sup>17</sup> in rats and by Greene<sup>18</sup> in rabbits. Instead of a cortical hyperplasia a degeneration of the adrenal medulla has been found to be associated in some strains with a high incidence of breast cancer.

#### COMMENT

This is only a brief outline of the various etiologic factors concerned in breast cancer. But it is sufficient to show that a new field for clinical and pathologic observations has been opened. The presence of a family history of breast cancer is an extremely valuable aid in the early diagnosis especially when the clinical or pathologic evidence is doubtful. Another problem of practical importance requiring solution is the question whether patients with breast cancer and a family history of breast cancer are more likely to develop a second primary tumor in the other breast. Further a thorough examination of the adrenals and the pituitaries at autopsies of patients dead of breast cancer and with a family history of breast cancer may reveal a group in which there is an association between breast cancer and abnormalities of these endocrines.

#### CONCLUSION

I began this lecture by asking the question: Why does a patient get cancer? We have been told often enough, even in recent times, that this question cannot be answered until the problem has been solved of the nature of the proximate cause of cancer—that is the nature of the intracellular changes by which a normal cell is transformed into a cancer cell. This belief engenders a pessimism which hinders further progress. The point I have tried to make in this lecture is that there is no longer a central problem of cancer on the

solution of which further progress depends. In fact, it is an error to think in terms of a central problem of cancer. From a correlation of the results obtained by the study of experimental carcinogenesis in animals with clinical and pathologic observations and with statistical investigations on cancer in man, it has become evident that there is a multiplicity of etiologic factors and that the etiology of cancer in man, as in animals, has to be considered as a separate problem for each organ.

In this way we are now beginning to trace cancer in man down to its various sources of origin. What is more, we are entitled now to consider the possibility of preventing several forms of cancer in man by attacking the disease at its origin instead of remaining on the defensive until the disease has attacked man. Further progress along these lines is possible by the same collaboration of the laboratory worker with those concerned with the study of cancer in man, which forty years ago established the curability of cancer in its early stage.

### RENAL CHANGES IN A CASE OF SULFADIAZINE ANURIA

H. A. BRADFORD, M.D.  
AND  
J. H. SHAFFER, M.D.  
DETROIT

Early in the treatment of pneumonia with sulfapyridine and sulfathiazole, attention was drawn to the side effects of those drugs on the kidney. Complications involving the urinary tract have been caused by obstruction of the ureters, kidney pelvis, calices and tubules by crystals of the acetylated form of the drug and secondly by toxic effects of the drugs on the kidney tissue. Changes noted in renal tissues were cloudy swelling and desquamation in the tubules.

Such changes were noted by Smith and Delaney,<sup>1</sup> who have recently reported 5 cases of pneumonia in which renal complications developed following treatment with sulfapyridine and sulfathiazole. Two patients

Fig 1—Clinical course of patient who received sulfadiazine for type III pneumococcus pneumonia

failed to survive and came to postmortem examination. In the first instance sulfapyridine was administered. Pathologic examination of the kidneys showed definite degenerative changes confined largely to the convoluted tubules. The second patient suffered from chronic

glomerulonephritis, contracted pneumonia and was treated with sulfathiazole. Postmortem examination showed cloudy swelling and desquamation in the tubules, in addition to those changes typical of glomerulonephritis. A third patient, a woman, suffered with anuria following sulfathiazole therapy. She recovered but

Fig 2—Sulfadiazine uroliths in the renal pelvis. Note ulceration of the adjacent pelvic epithelium with underlying zone of inflammatory reaction. Deposits of acetylated drug in the renal tubules in nearby area.

follow-up studies of the renal function suggested persistent evidence of minor tubular damage, although there was a complete restoration of glomerular function.

Early work on absorption, excretion and toxicity of the newer drug sulfadiazine by Feinstein,<sup>2</sup> Plummer<sup>3</sup> and others suggested that the drug would have the desirable qualities of sulfapyridine and sulfathiazole and at the same time fewer of the undesirable side reactions. Experimentally sulfadiazine was absorbed promptly after oral administration and gave relatively high blood concentrations, there was less acetylation and less toxic reaction on body tissue, especially in the urinary tract. The drug moreover, was just as efficient as sulfapyridine and sulfathiazole in controlling infection caused by pneumococci. Sulfadiazine was found to leave the blood stream slowly, elimination was largely through the kidneys.

Although published reports have appeared in the literature of series of sulfadiazine treated pneumonia patients, only 2 instances of anuria following the use of the drug have been noted. In his series of 44 cases Finland<sup>4</sup> reported renal colic, hematuria and anuria in 1 case, the patient responded to ureteral catheterization. A second case of anuria following sulfadiazine therapy for infection of the urinary tract was reported by Thompson,<sup>5</sup> his patient also recovered following ureteral catheterization.

The following report is that of a patient who received sulfadiazine for type III pneumococcus pneumonia. Administration of the drug was followed by renal manifestations characterized by hematuria, albuminuria,

sulfadiazine crystals in the urine, urinary suppression and azotemia followed by death. A pathologic study of the kidneys was obtained in this instance.

#### REPORT OF CASE

J. H., a Polish man aged 64, was admitted to the Henry Ford Hospital Oct 11, 1941 and died October 23. For years he had suffered from bronchial asthma. He had remained at home for one week prior to admission because of fever, malaise and a cough productive of large amounts of thick yellowish phlegm. The day before admission the temperature rose to 104 F and there was a chill with an associated pain in the anterior part of the chest.

The patient was slender and was obviously ill, with a temperature of 102 F, a pulse rate of 120 and a respiratory rate of 28. The lips and finger nails were cyanotic. His cough was productive of yellowish sputum. Examination of the chest showed impairment bilaterally over the lower lung fields with suppression of breath sounds; there were numerous moist rales. The blood pressure was 125 mm of mercury systolic and 65 diastolic. The abdomen was moderately distended.

The admission leukocyte count was 23,000, with 91 per cent polymorphonuclear cells. The urine was the color of light straw with a specific gravity of 1.018 and contained a trace of albumin. Microscopic examination revealed 1+ finely gran-

The blood sulfadiazine level was 12 mg per hundred cubic centimeters. The nonprotein nitrogen level had risen to 79 mg per hundred cubic centimeters and the urine contained 3+ sulfadiazine crystals and 4+ erythrocytes. The patient was given supportive treatment including oxygen, dextrose and saline solutions intravenously and small blood and plasma

Fig 4—Section under high power showing uroliths deposited in kidney parenchyma.

transfusions. For forty-eight hours preceding death the urinary output ceased and the blood nonprotein nitrogen rose to 131 mg per hundred cubic centimeters. The blood sulfadiazine level had dropped to 4.9 mg per hundred cubic centimeters. Permission for pathologic study of the kidneys only was granted. Necropsy was performed one hour post mortem by Dr. M. O. Alexander.

#### PATHOLOGIC EXAMINATION

The right kidney weighed 290 Gm and the left 305 Gm. The capsule of each kidney presented opaque areas but stripped with ease showing smooth purplish surfaces except for a few small cysts. The cut edges rolled, indicating the presence of edema. The cortex of the right kidney averaged 8 mm in width, that of the left 7 mm. The cortices and pyramids on each side were colored a light purplish gray while the latter contained linear vascular striations. The renal pelvises were not dilated and their lining surfaces were grayish red and congested. The pelvises contained a large amount of light

Fig 5—Sulfadiazine uroliths deposited in the peripelvic adipose tissue. Note dark zone of inflammatory reaction nearby.

brown, gritty material which on analysis contained 92 per cent acetylated, 6 per cent free sulfadiazine and 6 per cent protein.<sup>6</sup> The bladder contained about 50 cc of urine. The mucosa of the ureters and bladder appeared normal.

On section the capsule showed no evidence of inflammatory reaction. The glomeruli appeared normal except for slight engorgement of the capillaries. The periglomerular space was

<sup>6</sup> Chemical analysis on dry weight was done by the Bratton-Marshall technique.

Fig 3—Section under high power showing ulceration of epithelial lining of renal pelvis adjacent to acetylated drug deposit in kidney pelvis. Note zone of intense inflammatory reaction with associated hemorrhage, necrosis and polymorphonuclear and small round cell infiltration.

ular and 2+ coarsely granular casts. Sputum examination by the Neufeld rapid method yielded numerous type III pneumococci.

The patient was started on sulfadiazine (fig 1). He was given an initial dose of 3 Gm followed by 2 Gm in four hours, then 1 Gm every four hours thereafter. On the third hospital day the blood sulfadiazine level was 86 mg per hundred cubic centimeters and the temperature had returned to normal. Examination of the chest showed persistent impairment bilaterally with showers of medium moist rales in both impaired areas. The leukocyte count had decreased to 5,000. The urine contained 3+ sulfadiazine crystals and 3+ albumin. The blood nonprotein nitrogen was 34.5 mg per hundred cubic centimeters. Because the temperature had returned to normal and because of the urinary conditions and low leukocyte count sulfadiazine was discontinued; a total of 24 Gm had been given.

On the fifth hospital day the leukocyte count had risen to 24,350 cells per cubic millimeter with 84 per cent polymorphonuclear cells. The temperature rose to 101.6 F and there were physical signs of an extension of the pneumonic process in the right lung. Sulfadiazine was again started with an initial dose of 3 Gm, followed by 1 Gm every four hours. When the patient had received 26.5 Gm of the drug in the second course it was stopped because of an alarming decrease in the urinary output as is shown in the accompanying table. The total amount of the drug given was 50.5 Gm.

free of cellular content. Blood vessels in the medullary portion of the kidneys were very congested. An area of intense inflammation with extensive necrosis adjacent to the pelvis was noted. Here only was the renal tubular structure entirely destroyed.

Microscopic examination showed drug deposits in the pelvis of the kidney. Immediately adjacent to the drug deposit the epithelial lining of the pelvis was ulcerated. Beneath the ulcerated areas was an area of intense inflammatory reaction and necrosis, with extensive hemorrhage, polymorphonuclear and round cell infiltration. The remaining tubular epithelium was essentially intact except for certain areas which contained drug deposits and desquamation and swelling of the tubular epithelium.

Uroliths surrounded by polymorphonuclear and small round cells were present within the renal pelvis and in several areas occupied the marginal zone of necrotic tissue. Numerous uroliths appearing to have a crystalline structure were present in the renal pelvis and within the urinary papillae.

#### COMMENT

The histologic appearance of the kidneys in this case in which sulfadiazine therapy resulted in anuria resembled that produced experimentally by Antopol and his

Plummer and McLellan<sup>9</sup> and Stryker<sup>10</sup> referred to the occurrence of sulfapyridine calculi within the renal pelvis and calices but noted no zone of surrounding intense cellular reaction. Stryker and others<sup>11</sup> have also described the collection of plugs of sulfapyridine within the renal tubules.

The case herein presented showed many sulfadiazine uroliths in the renal pelvis and renal papillae with an associated necrosis and inflammation in the surrounding tissue. There was some swelling and desquamation in the tubules, some of which contained deposits of the drug. In areas adjacent to the drug deposits, renal tubular structure was entirely destroyed. Hematuria was an accompanying clinical evidence of crystalluria.

This case does not illustrate a favorable result in the sulfadiazine therapy of pneumonia. The total amount of the drug given was not optimal. Cystoscopy and irrigation of the ureters was not performed initially when there was a diminution of the daily urinary output, and later, when anuria occurred, the precarious condition of the patient made this procedure of doubtful

associates<sup>7</sup> with sulfonamide drugs. Rats given single lethal doses of sulfathiazole or sulfapyridine showed an accumulation of precipitated noncrystalline free drug within the urinary tract. On the other hand, in animals in which sulfonamide administration was prolonged resulting uroliths were composed of acetylated drug. The authors used the term "calcifying nephrosis" to describe the reaction in the tissue zone adjacent to the drug deposits. Special staining demonstrated calcium deposition not only in the zone adjacent to the tubules but also within the lumen. Intense inflammatory changes and extensive necrosis occurred in tissue surrounding the drug deposit when the accumulations were not removed by irrigation within twenty-four hours.

Recently Gross, Cooper and Hagen<sup>8</sup> reported occurrence of urolithiasis in rats given sulfadiazine and postulated that this complication would also be observed in man. They concluded that crystal deposition took place almost exclusively within the renal tubules. They commented on the absence of hematuria because of the fan-shaped, rounded contour of the crystals and also on the absence of tissue trauma because of imprisonment of crystals within the tubular structures.

therapeutic value. Impending renal complications may be suggested by the failure of the urinary output to increase as clinical improvement occurs.<sup>12</sup>

#### CONCLUSIONS

1 Sulfadiazine therapy for type III pneumococcal pneumonia in a man resulted in urinary suppression and death.

2 Postmortem examination was limited to a study of the kidneys.

3 In the portions of kidney tissue adjacent to deposits of acetylated sulfadiazine, tissue damage was in evidence. Changes noted were ulceration through the epithelium lining the renal pelvis, with an associated area of intense inflammatory reaction and necrosis. The precipitated drug was also noted in the renal tubules; some tubules were swollen and desquamated.

4 There is need for early ureteral catheterization and pelvic lavage when one is confronted with renal complications associated with sulfadiazine therapy.

VENOUS ANGIOMAS OF SKELETAL  
MUSCLE

REPORT OF FOUR CASES

MARSHALL N. FULTON, M.D.

AND

MERRILL C. SOSMAN, M.D.

BOSTON

An angioma may be defined as a tumor mass composed of vascular channels and spaces (arterial, venous, capillary or lymphatic), nearly always of benign nature arising in various areas of the body. There is divergence of opinion as to the nature of these growths. By some they are considered as true tumors and it is well known that they may grow and exhibit the characteristics of a malignant neoplasm. By others, however, they are looked on as a simple malformation—a mass of “swollen blood vessels”—in some instances, at least clearly related to injury. Their course is variable, many remaining stationary some actually disappearing spontaneously. Though the majority are congenital in origin they often do not produce symptoms until the age of late childhood or early adult life.

The features of angiomatous malformations in different regions of the body have been adequately covered in the literature. Davis and Kitlowski<sup>1</sup> and subsequently Jenkins and Delaney<sup>2</sup> reviewed in detail the subject of angiomatous tumors of skeletal muscle, bringing up to date reports from the literature on some 250 cases. The classic monograph of Cushing and Bailey<sup>3</sup> published in 1928, dealt extensively with blood vessel tumors arising in the brain. In 1930 Bucy and Capp<sup>4</sup> made a comprehensive study of primary hemangiomas of bone, recording their observations in a series of 8 cases and emphasizing particularly the roentgenologic aspects. Pierson, Farber and Howard<sup>5</sup> reported a case of multiple hemangiomas of bone, probably of congenital origin. Other contributions in the recent literature include the study of Matas<sup>6</sup> on arteriovenous angioma of the arm with metastases, of Hampton and Sampson<sup>7</sup> on angioma of the tympanic cavity, of Oughterson and Tennant<sup>8</sup> on angiomatous tumors of the hands and feet and of Kevorkian<sup>9</sup> on hemangioma of the uterus. The recorded cases of angiomas of the skin and their treatment are legion.

Our purpose in this communication is to report 4 cases of angioma of skeletal muscle that have recently come under our observation, emphasizing particularly their roentgenologic characteristics. While this condition is not of extreme rarity, it occurs infrequently, and many are unfamiliar with the clinical and roentgeno-

logic features. The latter, because of the presence of phleboliths in the angioma, are almost pathognomonic. Once the condition has been encountered it is not likely, subsequently, to present any difficulty in diagnosis.

**CASE 1**—*Venous angioma of the right arm just above the elbow. Recurrent attacks of pain and swelling for thirteen years. Diagnosis by roentgen examination confirmed by injection of diadrasol. Roentgen therapy.*

M. L., a housewife aged 23, was referred to us in October 1940 by Dr. John Thompson because of pain and swelling in the region of the right elbow. At the age of 10 she first became aware of trouble with this elbow in association with an infection which she thinks was a cold. Her elbow was “stiff,” swollen and painful at that time. The condition persisted for about two weeks and was called inflammatory rheumatism. Ever since then on two or three occasions each year the patient had had an episode of pain, swelling and stiffness in the elbow lasting two to five days. The arm also seemed to be somewhat stiff and troublesome at times during rainy weather. She had had none of this for nearly two years until the present episode and though there had always remained some slight residual swelling in the elbow, there had been no persistent pain in it and she had been able to carry suitcases or heavy weights

Fig. 1 (case 1).—Multiple phleboliths in the noncircumscribed angioma above the elbow joint. The bones are normal.

with her arm extended. About three weeks before without any trauma or other precipitating cause, the arm at the elbow became swollen over a period of three or four days. The patient applied hot applications and a liniment and the swelling subsided somewhat though tenderness and pain on motion persisted. She at first took sulfanilamide, and this seemed to have some good effect.

During the latter part of this three week illness she had had pain in both knees and in the posterior aspect of both heels. This pain had been very bad at times, necessitating her staying in bed but had subsided following salicylate therapy. She had had elevation of temperature as high as 102 F during the acute stage of her illness.

The right arm showed a moderate fusiform swelling in the region of the elbow, maximal over the joint and extending 3 or 4 cm below and 6 or 7 cm above. The arm was least painful with the elbow flexed at about 110 degrees. There was extreme pain on motion of the joint which made it impossible to determine the extent of limitation of motion. There was no evident discoloration of the skin. Nothing other than moderate tenderness and some increase in local temperature could be made out on palpation. No bruit was audible over the swelling. Except for some pain on motion of the knees tenderness over the attachment of the Achilles tendon and moderate generalized pallor of the skin and mucous membranes, the rest of the physical examination was negative. The tem-

perature was normal, the pulse rate, 90. The red blood cell count was 3,780,000, the white count 6,200.

An x-ray film (fig 1) taken a short time before the patient was seen showed the unusual condition evident in the illustration, namely, multiple dense rounded shadows in the soft tissues above the elbow, several of them laminated, the largest one about 6 mm in diameter. These were recognized as phleboliths, their presence in this region indicating a venous angioma. There was no evidence of disease of the joint itself or of the bones. (Even with this added information, one could not palpate any nodules in the swelling above the elbow.)

With continuance of local heat to the arm and salicylates, the patient made a prompt recovery, the discomfort disappearing in her lower extremities within a few days, the pain, tenderness and swelling in her arm gradually subsiding over a period of a week. At the end of this time the patient had no complaints referable to her arm other than her inability to straighten it beyond about 160 degrees, and pain on relatively slight traumatization. It was believed that this attack, similar in kind to the others she had had intermittently over a period of ten years, but of much greater intensity, represented an inflammatory reaction in the venous channels of the angioma, probably a thrombophlebitis. The nature of the trouble in her knees and ankles was not clear. This, she repeatedly attested, was the first time any joints other than the right elbow had ever been involved during an attack. It was thought possibly to represent a toxic reaction in the knee joints and at the site of attachment of the achilles tendon.

Several weeks after the patient had recovered, in an effort to substantiate the diagnosis of angioma, an injection of Diodrast Compound Solution (50 per cent diodrast)<sup>10</sup> was made in a vein on the medial side of the wrist with a tourniquet applied high up on the upper arm. X-ray films (figs 2 and 3) showed the extraordinary plexus of veins making up the angioma and several large venous lacunae near the periphery. These, furthermore, showed the extent of the angioma and made clear the difficulties that would be encountered in attempting excision of the tumor. Because of the size and location of the lesion

Fig 2 (case 1)—Lateral view during injection of diodrast after injection (a) of 10 cc, (b) of 20 cc. Note large lacunae and extensive anastomosis of venous channels.

plus the patient's objection to any operative procedure, roentgen treatment was carried out. The rationale of this therapy is based on the known effect of roentgen irradiation on angiomas in the skin and those in the brain, as seen, treated and followed up in Dr Cushing's service. The factors used and the doses given were as follows: 200 kilovolts, 50 cm skin-target distance, 0.5 mm of copper and 1 mm aluminum filter, 18 milliamperes current, constant potential full wave rectification.

Treatments were given twice a week beginning November 4 and ending November 29. Each treatment was of three minutes' duration (200 roentgens) and the fields were alternated medially and laterally, including all of the demonstrably abnormal vessels. The total dose was 800 roentgens to each of two surfaces over the tumor.

There was no clearcut objective or subjective improvement following this treatment. When examined several weeks after the last treatment, the patient stated that she had experienced no discomfort in her arm, save for slight pain in the region of the elbow if she attempted to straighten out the arm by force. The right elbow region still showed a slight fusiform swelling with some increase in local skin temperature. The most noticeable swelling was just lateral to the olecranon process. Over this area the skin showed a faint bluish discoloration, and there was a soft, nontender jelly-like mass palpable just beneath the skin. No nodules could be felt, and, again, no bruit was audible.

As a means of evaluating the effect of roentgen therapy a second injection with diodrast was made three and a half months after the last roentgen treatment. During this interval the patient had been symptomless, no obvious change in the appearance of her arm had taken place. Figure 4 indicates the condition of the angioma at this time. With the same amount of diodrast injected, there appeared to be a much less extensive anastomosing plexus of blood channels. Encouraged by this apparent improvement, we have carried out a second series of roentgen treatments with the same dosage as before. The treatments were completed on April 21, 1941, without any apparent effect. Except for two minor attacks of pain and stiffness since that time the patient has been free from symptoms other than pain on forced extension of the elbow beyond 160 degrees.

**CASE 2—Venous angioma of the left arm just above the elbow, previously diagnosed fatty tumor. Persistent nontender swelling for sixteen years. Diagnosis by roentgen examination. Surgical excision.**

S. J., a woman aged 32, single, was referred for an x-ray examination of the left elbow by Dr William T. Green, who gave permission to publish the details in this report. The patient stated that at about the age of 16 she became aware of a small swelling just above the left elbow on the inner aspect of the arm. A small mass of tissue was removed from this area which she was led to understand was a "fatty tumor." The operative wound healed normally. During the subsequent years a slight nontender swelling had persisted in this region which would ache at times after she had exercised her arm, though never so as to incapacitate her. For three or four years the skin over this swelling had occasionally exhibited a variable degree, so she thought, of bluish discoloration. Some two weeks before being seen there had occurred, without obvious cause, a dull aching pain just above the elbow. There were also associated twinges of pain radiating down the forearm from the hand to the little finger. She had suffered no loss of strength or limitation of motion in the arm, but she considered the swelling to be larger than usual.

Examination revealed a soft, slightly tender mass approximately 7.5 by 2 cm in size just above the inner aspect of the left elbow. The skin over the mass had a faint bluish discoloration, and within it could be felt several small hard nodules.

Fig 3 (case 1)—Anteroposterior view following injection of 20 cc of diodrast showing, better than the lateral view, the extent of the angioma, lacunae and component vessels.

<sup>10</sup> The Winthrop Chemical Company, Inc., New York supplied the Diodrast Compound Solution used in this study.

Pressure did not produce pain locally or along the course of the ulnar nerve. There was no limitation of motion or abnormal mobility. No murmur could be heard over the mass.

X-ray examination of the elbow (fig 5a) showed a smoothly outlined oval tumor just above the medial condyle of the humerus measuring 1.5 by 6 cm in size. Within the tumor were multiple phleboliths of varying size and density. The tumor was considered, because of these a venous angioma. A film of the other elbow showed no variation from normal.

Gaseous anesthesia was administered and with a tourniquet applied above the tumor dissection was carried through the deep fascia. The tumor was found to be made up of a mass of blood vessels invading the triceps muscle and growing around the ulnar nerve. A clean dissection was carried out which necessitated opening the nerve sheath, and it was possible for the operator to remove what he considered to be the entire tumor. Postoperatively the patient experienced numbness of the fourth and fifth fingers of the left hand with loss of power to abduct these fingers. This persisted for several days but gradually cleared up entirely. The wound healed by first intention.

The tumor showed on gross pathologic examination muscle and connective tissue containing several phleboliths measuring up to 7 mm in diameter. Sections of the tissue revealed that it was a cavernous hemangioma containing organizing thrombi.

The patient has had no recurrence of any trouble during the two and a half years since operation. Roentgenograms taken at the end of this interval (fig 5b) show complete disappearance of the phleboliths and normal soft tissues and bones in the region of the elbow.

**CASE 3—Venous angioma of left forearm and hand with involvement of phalanges and metacarpal bones. Enlarged veins of fingers, hand and forearm since birth. Periodic swelling following exercise. Diagnosis by roentgen examination. Roentgen therapy.**

Fig 4 (case 1)—Anteroposterior view following injection of 20 cc of diodrast three and one half months after roentgen irradiation. Note the apparent decrease in the intercommunicating vessels. (Compare with fig 3.)

R. M., a youth aged 18, a stenographer, was first seen in the surgical service of this hospital in 1929 complaining of a painful swelling of the left hand and forearm with subcutaneous hemorrhages on the palmar surface. It had been noted a few weeks after his birth that there were numerous enlarged veins on the palmar surface of the three medial fingers of the left hand and on the palm and ventral surface of the left forearm. These caused no particular difficulty but as the patient grew up he noticed that following the use of his arm in such activities as heavy lifting, shoveling or rowing a boat the arm and hand would exhibit painful swelling that would persist for varying periods of time. On one occasion after the administration of diphtheria antitoxin there had been much swelling. The enlargement necessitating his present admission had come on four days before following the handling of some heavy boxes. The arm and hand in addition to being swollen had seemed to turn a bluish red and he had noted considerable pain on moving the fingers or wrist. There had been no throbbing and no general constitutional symptoms. There was no history of any similar trouble in other members of his family.

The patient was large and muscular. Physical examination apart from the left arm and hand showed no significant abnormality. The left arm from the elbow down was swollen, reddish blue, distinctly warm to the touch and tender. In the hand the swelling involved the palm and the palmar surface of the three medial fingers. The dorsal surface and the thumb and

index finger were not noticeably affected. There were minor subcutaneous hemorrhages in the swollen parts. The radial pulses were equal. Enlarged veins were noted by one observer in the left axilla. The appearance of the arm and hand is shown in figure 6. Laboratory studies of the urine and blood, including bleeding and clotting time, were normal. During his weeks stay there were occasional mouth temperatures of 99.4 and 99.6 F. X-ray examination (figs 7 and 8) showed

Fig 5 (case 2)—Multiple phleboliths of varying size and density completely removed by operation. a before and b two and one half years after surgical excision of circumscribed angioma.

multiple phleboliths of various sizes in the left forearm and palm (none in a control film of the right arm). Several of the bones of the hand showed a peculiar honeycombed appearance, particularly the second phalanx of the fifth finger, less marked in all three phalanges of the ring finger and slight in the third, fourth and fifth metacarpals. The other bones appeared normal. These findings were considered indicative of an angioma of the left forearm and hand and a similar type of lesion in several of the bones.

The arm was treated for a week by elevation and hot soaks with resulting reduction in the swelling, discoloration and tenderness. Further diminution was evident when the patient was seen again a month later for discussion as to the most advisable therapy. The condition was considered a congenital venous hemangioma of the forearm and hand, far too extensive to allow for surgical excision. The periodic swelling was looked on as the result of venous stasis probably with associated inflammatory reaction (thrombophlebitis). Treatment by roentgen irradiation was undertaken, the patient receiving five double treatments of 700 roentgens in each series, two of them only to the fifth finger and three series to the entire forearm and hand over a period of ten months. The treatments were given with medium voltage (140 kilovolts), 40 cm target-skin distance and 0.25 mm of copper filter. No definite improvement was noted from this, and treatments were therefore discontinued.

The patient was lost sight of during the twelve year interval, having moved meanwhile to a distant locality. He has recently informed us by letter that there is no apparent change in the condition of the hand and arm. On occasions when he may bruise or use it excessively there may be swelling which is mildly painful. This, he adds, is the way it acted in the past. X-ray films secured this year through Dr. E. L. Voke of Akron, Ohio, show a diminution in the number of phleboliths in the forearm, one additional one in the palm and considerable improvement in the bone lesions.

**CASE 4—Venous angioma of sole of right foot with symptoms of four years' duration and development of phleboliths during this interval. Diagnosis by roentgen examination. Surgical exploration. Roentgen therapy.**

W. F. B., a grocery clerk aged 20, was first seen in the surgical outpatient department at the age of 16 complaining of pain in the longitudinal arches of both feet, especially the

right There was no history of trauma or infection Examination showed only bilateral pronation and some swelling and tenderness over both calcaneoscaphoid regions An x-ray film showed no apparent variation from normal There was improvement with strapping, foot exercises and a heel lift to both shoes He was lost sight of but returned after four years, stating that he had had occasional discomfort in the sole of the right foot with walking but that for three months, without obvious cause

Fig 6 (case 3)—Appearance of forearms and hands, showing swelling and blotchy discoloration of the palm and three medial fingers of the left hand

for aggravation, there had been rather severe pain in the same region, with a persistent ache in the foot even when he was quiet in bed On examination there was evident swelling of the sole of the foot with tenderness on moderate pressure over the midportion but no discoloration of the skin The patient was unable to plantar flex his toes normally The left foot appeared normal except for slight pronation An x-ray examination at this time (fig 9) showed a diffuse slight swelling involving almost the entire extent of the longitudinal arch with two rounded dense shadows in the middle part of the swelling which were thought to be phleboliths Because of these, a presumptive diagnosis of venous angioma was made

Under spinal anesthesia an exploratory operation was carried out which revealed an obvious angioma composed of large tortuous vessels contained in strands of dense connective tissue occupying the so-called second muscle layer of the foot It was judged too extensive for dissection A small piece of tissue removed for microscopic study was unsatisfactory The operative wound healed normally

Following operation the patient received roentgen therapy daily for ten days, the dosage employed being the same as that in case 1, the total dose being 1,000 roentgens to each of two surfaces over the tumor When seen six weeks after this treatment he reported very definite improvement, stating that he experienced pain in the foot only after running and that this lasted for only a few minutes The appearance of the foot was unchanged

#### COMMENT

These 4 cases serve to illustrate the course and some of the features of venous angiomas In each of the first 3 instances there was a history of swelling of the arm noted since childhood, with periodic episodes of

pain, tenderness and increased swelling The diagnosis in each of these cases was established by the roentgenologic demonstration of sharply defined calcified phleboliths within the tumor This finding clarified in the first case what had been looked on as a recurrent, monoarticular arthritis, in the second, as a fatty tumor of the arm In case 4 the finding of phleboliths in the second x-ray examination which were not present four years previously made evident the nature of the swelling in the foot

The occurrence of phleboliths, particularly in the veins of the pelvis, is, of course, extremely common and their recognition by roentgenologic examination is an almost daily experience The phleboliths result from the deposition of calcium in organized thrombi attached to or within the wall of the vein A number of these calcified shadows in x-ray films in areas of the body where there is normally no plexus of veins is indicative of an abnormal collection of venous channels and is to all intents and purposes pathognomonic of a venous angioma While this fact is well known to experienced roentgenologists and is described in standard textbooks on x-ray interpretation,<sup>11</sup> it is not a condition of common enough occurrence to be recognized generally Where the mass of vessels is sharply circumscribed, as in case 2, a definite tumor mass may be outlined within the surrounding muscle In other cases the malformation may extend diffusely through the tissues so as not to be recognizable as a localized tumor There may, of course, be no phleboliths present, in which case the roentgenologic examination may show no more than a swelling or tumor of the soft tissues

One may summarize the general facts concerning venous angiomas of skeletal muscle as follows They occur with about equal frequency in the two sexes In the great majority of instances the malformation is noted during childhood or early adult life, a fact which indicates their probable congenital origin Just how much trauma has to do with their development is not clear In some instances, doubtless it does no more than call attention to a preexisting lesion, perhaps by initiating a reaction leading to thrombosis within the veins and cavernous spaces of the tumor It is certainly true that patients are commonly made aware of their angioma following minor injury There is no doubt that motion plays a big role in the growth of the tumor<sup>12</sup>

Fig 7 (case 3)—Widely scarred forearm. The bones are normal

<sup>11</sup> Holmes G W and Ruggles H E Roentgen Interpretation, 6 Philadelphia Lea & Febiger, 1941 p 21

The tumor may occur in any striated muscle. The fact that 3 of our 4 patients had theirs in the arm emphasizes unfairly this site for the tumor. In the large series reported<sup>2</sup> the upper arm was the site of location in 22 instances compared to 59 in the thigh, 39 in the lower leg, 36 in the chest and 26 in the forearm. The most frequently involved muscle was the

Fig 8 (case 3)—Phleboliths in the palm and honeycombed appearance of several phalanges and metacarpals due to angiomas in these bones

quadriceps extensor. The size of the tumor varies from 1 to 2 cm up to a mass 10 to 12 cm in diameter or larger. Microscopic study shows enlarged venous channels and cavernous spaces, some lined by a single layer of epithelium and some showing considerable thickening of the intima or adventitia. These contain either normal blood or thrombi, with or without calcification. There may be deposition of considerable fibrous connective tissue and the remains of striated muscle fibers are commonly present showing various stages of degeneration.

The symptoms complained of will vary from none at all to those of considerable magnitude. Pain is the commonest in some instances related to muscular movement (which may be impaired), in others, arising from nerve pressure and following a sensory nerve distribution. Paresthesias and numbness, and periodic or constant swelling are common. The physical attributes of the tumor likewise differ according to its size and location. There is occasionally fixation of the overlying skin and the latter may be warm to the touch and may exhibit some degree of bluish discoloration. The mass often is soft, jelly-like and movable, sometimes quite firm and fixed. As already noted, it may be fairly sharply localized when encapsulated or may be diffuse. The phleboliths at times are easily palpated. Rarely are pulsations or bruits to be made out unless there are free arteriovenous communications.

The differential diagnosis will include the common tumors which have some of these physical character-

istics, namely lipomas, fibromas and so on as well as quite dissimilar conditions—cold abscess, hematoma, dermoid and even aneurysm. The diagnosis is not always easy, and the true nature of the lesion often is recognized only at operation. Three procedures are helpful in clarifying the diagnosis:

- 1 Exploratory puncture with aspiration of normal blood

- 2 The intravenous injection of radiopaque solution, as used in case 1. This measure is of particular help in diagnosis when phleboliths are not present. It is of value in demonstrating the extent of the angioma and may also assist in determining the effect of roentgen therapy. Obviously it is applicable only when the angioma is so located that a tourniquet can be placed proximal to the tumor to prevent the immediate dissemination of the injected material into the general circulation.

- 3 Most helpful of all, roentgen examination. On the x-ray film the venous angioma may show as a distinctly outlined mass (case 2) or simply as a diffuse soft tissue swelling (cases 1, 3 and 4). The characteristic and practically pathognomonic finding is the presence of phleboliths. These appear as small, dense, smoothly outlined areas heavily calcified, either round or slightly oval, often showing concentric laminations. As noted, they are commonly seen in the pelvis, particularly in elderly people, more frequently in women than in men, and also in the spleen. The calcified shadows in the spleen are usually smaller, rounded and not laminated and may be interpreted as calcified tubercles or calcified infarcts, which they may be on occasion. The pentastomum, a parasitic arthropod, may lodge in the spleen and undergo calcification, forming nodules the size of a pea, commonly mistaken for phleboliths. Phleboliths are occasionally seen singly in the lower part of the legs of elderly patients, especially if varicose veins are also present. When three or more phleboliths are seen grouped together in an unusual location such as an extremity or the chest or abdominal wall, the logical conclusion is that one is dealing with an abnormal collection of veins, usually, of course, a venous angioma.

The differential diagnosis from other calcified bodies is usually quite easy, owing to their characteristic size,

Fig 9 (case 4)—Right foot four years after original complaint of pain showing phleboliths in the sole of the foot not present four years previously

shape, structure and density. Droplets or particles of metallic substances used in medication, such as bismuth or mercury, are definitely more opaque to the x-rays, more irregular in distribution, not laminated and nearly always found in the buttocks. Calcified parasites rarely are confused with phleboliths, the trichiniasis parasite being too small to show by x-ray except in excised pieces of muscle. The cysticerci, when calcified are

smooth in outline but oval, measuring 2 to 4 mm in width by 8 to 10 mm in length. They are not as dense as phleboliths, are finely granular in appearance and do not show a laminated structure. They are rarely present in groups, being widely scattered throughout the body. The guinea worm (*Diacunculus medinensis*) frequently calcifies but is not in any way similar to phleboliths and is seen only in India, Asia and some parts of Africa.<sup>12</sup> Lymph nodes, arteries, tubercles, infarcts, abscesses, uterine fibroids, dermoids and hydatid cysts may undergo calcification but are not of the size, shape or distribution to be confused with phleboliths. Calcinosi interstitialis and myositis ossificans are irregular and streaky in distribution. The former frequently is limited to the skin and subcutaneous tissue, the latter may be limited to one muscle or one group of muscles and tendons. They are not at all similar to calcified phleboliths.

The treatment most generally advised for angiomas of this type is surgical excision. Removal when feasible should be carried out as early as possible to reduce the danger of functional impairment of the part and prevent the growth or extension of the tumor. Surgical excision is not always simple, indeed at times is impossible because of the extent of the angioma (as in cases 3 and 4). Difficulties commonly encountered in surgical removal arise from the extension of the angioma so that it involves important neighboring structures such as nerve trunks, which may be damaged during the dissection of the tumor. Hemorrhage of appreciable magnitude may occur in the course of operative removal, as happened in the case reported by Jenkins and Delaney.<sup>2</sup> They state that hemorrhage "of considerable moment" occurred during surgical excision in 38 of the cases reviewed by them. Venous angiomas are rarely supplied by a single large vessel, so that ligation has not proved a successful form of therapy in inoperable cases. According to Davis and Kitlowski, such measures as long continued compression of the angioma or the injection of sclerosing or coagulating fluids have not been satisfactory. These authors also question the effectiveness of roentgen and radium treatment. Our experience with roentgen irradiation of angiomas of this type has been limited and, in the main, disappointing. The results noted in the cases reported in this paper, in which surgical excision did not seem advisable, have not been striking except in case 4. Certainly there is less effect in this type of angioma than in angiomas of the brain and skin, which often show very good response to irradiation. This may be due to the difference in size of the vessels involved. The smaller and more embryonic in type the vessels are, the more readily they are affected by irradiation.

#### SUMMARY

In 4 cases of venous angioma of skeletal muscle the diagnosis was made by the x-ray demonstration of phleboliths in the tumor. The finding of multiple phleboliths in areas of the body where normally no plexus of veins exists is practically pathognomonic of a venous angioma.

The value of a radiopaque material in delineating the extent of the tumor was illustrated in 1 case.

The treatment of choice is early surgical excision. Roentgen therapy may be of benefit and should be tried in instances in which surgical excision is inadvisable or impossible.

## THE USE OF MICROCRYSTALS OF SULFATHIAZOLE IN SURGERY

LESLIE A. CHAMBERS, PH.D.

T. N. HARRIS, M.D.

FRANCIS SCHUMANN, M.D.

AND

L. KRAEER FERGUSON, M.D.

PHILADELPHIA

In certain procedures it is desirable to inject neutral suspensions of the sulfonamides through fine hypodermic needles. Usually this is not possible with suspensions of the drugs currently available because of the large size and irregular shapes of the crystals. Dr. B. F. Souders and Dr. S. Brand Rose independently suggested that the crystals might be comminuted by sonic vibration. Direct vibration of suspensions of the preformed crystals produced no measurable effect, but an indirect procedure involving sonic agitation has been developed which reduces the crystal size sufficiently to permit passage through 26 gage needles.

Essentially, the preparation of the microcrystalline sulfonamides consists in the neutralization, at low temperature, of a solution of a sodium salt of the drug, the reacting mixture being kept in violent agitation by sonic vibration or by some suitable high speed mixing device. The size of the resulting crystals may be regulated within wide limits by controlling the speed of admixture or the temperature of the reactants or both. The microcrystals are fairly uniform in size, and aqueous suspensions of the material in concentrations up to about 30 per cent by weight are stable and show but little tendency to settle out.

A 20 per cent suspension of the microcrystalline drug in water or salt solution has the consistency of thick cream or magnesia magma. On the other hand, the water may be removed by filtration or centrifugation and the sediment dried to a fine powder. Both wet and dry preparations have physical properties of probable advantage in restricted therapeutic procedures.

It is obvious that the saturation level of a drug in tissue fluids will be the same no matter what the original crystal size, but the rate of attaining that level in the case of a substance of low solubility such as sulfathiazole is dependent on the total solid surface presented to the fluid and therefore on the size of the drug particles. When applied locally, the rate of solution of large crystals may be too low to maintain a saturation level in the adjacent tissue. On the other hand, the same amount of sulfathiazole, finely divided, may have a sufficiently high rate of solution to maintain saturation in nearby fluids, or even to maintain a fairly high systemic blood level for several hours.

As a reasonable approximation, it is probably safe to assume that the occurrence of a high sulfathiazole level in the blood of an experimental animal after local implantation of the drug indicates that much higher concentrations exist in the immediate vicinity of the depot. Therefore we have compared the rates of absorption into the blood stream of the microcrystals and the untreated macrocrystals in a series of experiments on dogs and rabbits after implantation of the drug both intramuscularly and intradermally.

The microcrystalline sulfathiazole used in this study was prepared by the French Laboratories of Philadelphia, supplied by and the work aided by a grant from the French Laboratories of Philadelphia.

From the Johnson Research Foundation and the Surgical Department of the Philadelphia General Hospital, the Hospital of the University of Pennsylvania and the United States Naval Hospital at Philadelphia.

muscularly and intra-abdominally. The average blood levels were considerably higher for the micro than for the macro preparations especially during the first few hours after administration. These data were obtained on a total of 23 rabbits 15 of which received micro-sulfathiazole intraperitoneally and 8 of which received macrosulfathiazole by the same route. The dose in each instance was 500 mg per kilogram of body weight and the drugs were in the form of 20 per cent aqueous suspensions.

Similar differences in absorption have been observed in a series of rabbits which received the same amount of the two types of drug suspension intramuscularly, but the absolute level in the blood was much lower in both cases than those which resulted from intra-abdominal implantation. No gross local reactions were observed in any of these animals, and it was not possible to locate the site of the implantation on dissection of the muscle ten days subsequent to the injection.

A similar difference in the rate of absorption of the two drugs has been observed in a series of 10 dogs. However, all of these results should be regarded as preliminary to a more extensive study, the results of which must await completion of more experiments. No inference should be drawn at present beyond the apparent fact that the microcrystalline sulfathiazole is absorbed from local depots more rapidly than is the same drug in macrocrystalline form.

Although sulfanilamide received early and deserved recognition as a local application in the prophylaxis and treatment of infections, its action against many of the contaminating organisms was less effective than had been hoped for. Experimental and clinical observations have shown it to be only weakly effective against staphylococci, colon bacilli and the gas gangrene organisms. In war wounds treated with sulfanilamide, those not responding well were found to be heavily infected with staphylococci.<sup>1</sup>

Sulfathiazole, however, appears to be an ideal compromise. It is effective in proper concentrations not only against the streptococcus but also against the staphylococcus, the colon group *Pseudomonas aeruginosa*, *Proteus vulgaris*, *Clostridium perfringens*, *Clostridium septicum* and *Clostridium oedematiens* and even in a measure against the tetanus bacillus.<sup>2</sup>

These are the common organisms causing local infections. They are also the common contaminating organisms in acute traumatic wounds. Pirlaski, Meleney and Spaeth,<sup>3</sup> in a recent paper on the bacterial flora

TABLE 1—Cultures Found in Two Hundred Traumatic Wounds

|                       | Per Cent |
|-----------------------|----------|
| Staphylococcus albus  | 81       |
| Staphylococcus aureus | 52       |
| Streptococci          | 50       |
| Clostridia            | 23       |
| Enterobacilli         | 24.5     |

of 200 traumatic wounds, reported cultures which may be summarized as in table 1.

The use of sulfathiazole locally has considerable experimental and clinical support. The most voluminous literature from the experimental side concerns infections with the organisms of gas gangrene. The

consensus<sup>4</sup> seems to be that sulfathiazole is the most effective of the sulfonamide drugs, although Bliss, Long and Smith<sup>2</sup> believe that sulfadiazine may be a little better.

It is agreed by most writers that sulfathiazole is highly effective against staphylococcal infections,<sup>5</sup> this even in the presence of pus and slough. Kennedy,<sup>6</sup> Kev,<sup>7</sup> Hawking<sup>8</sup> and Brunner and Schlappfer<sup>9</sup> have

TABLE 2—Solubility of Sulfanilamide and Sulfathiazole in Saline Solution and in Serum

|               | Solution in Saline at 37 C<br>Mg/100 Cc | Solution in Serum at 36 C<br>Mg/100 Cc |
|---------------|---|--|
| Sulfanilamide | 1 500                                   | 1 500 ±                                |
| Sulfathiazole | 104                                     | 184                                    |

urged its prophylactic use in traumatic and surgical wounds. The latter authors<sup>7</sup> report 109 wounds of varying degrees of depth and extent in which only the ragged edges of the wound were excised and sulfathiazole powder was applied. The wounds healed without inflammatory reaction, and recovery was not delayed. Sulfathiazole applied locally does not produce necrosis in experimental wounds and only very slight depression of fibroblast formation.<sup>10</sup> We have confirmed this observation in experimental wounds and clinically. In the abdominal cavity, Throckmorton<sup>11</sup> found that powdered sulfathiazole did not cause peritoneal damage but was grossly visible in agglutinated masses in the omentum three to six days later.

The chief theoretical disadvantage against the use of sulfathiazole is its tendency to clump and form insoluble masses which may act as foreign bodies in the tissues. As compared to sulfanilamide the drug is much less soluble in watery solution (saline) or in serum (table 2).<sup>10</sup>

The relatively low solubility in some respects may be an advantage in that the drug persists in the wound for four or five days. These results made Hawking<sup>10</sup> conclude that "probably the optimum combination of high concentration plus sufficient duration is by sulfathiazole," when compared with sulfanilamide, sulfapyridine or sulfadiazine.

#### CLINICAL RESULTS

The clinical results to be reported must be looked on as clinical impressions, they may be criticized on the basis of their small number. Nevertheless our reactions to the use of the microcrystalline drug have been so favorable that they seemed worth while mentioning. We have had considerable experience with

the use of sulfanilamide and ordinary sulfathiazole powder in wounds and local infections, and it is on the basis of this comparison that our clinical impressions are formed.

The microcrystalline sulfathiazole was used in the form of a powder and as a suspension in saline. The latter preparation, which in 10 or 20 per cent strength looks and behaves somewhat like magnesia magma, was used to be introduced into the abdomen or into larger cavities of wounds or abscesses. It can be easily injected through needles or with a syringe and catheter through small wound openings so as to reach all parts of a cavity. This ease of introduction and the avoidance of clumping are the chief advantages of the preparation. The crystalline powder was dusted over the surface of superficial wounds and infections with a powder blower or lightly spread with a cotton swab.

#### USE IN TRAUMATIC WOUNDS

We have used the microcrystalline sulfathiazole in 30 traumatic wounds. From 0.5 to 4 Gm. of the powder or suspension was introduced according to the size of the wound. All wounds were seen and treated within twenty-four hours, most of them within eight hours. Four of the wounds were complicated by division of tendons and three by compound fractures. The wounds were treated by a thorough mechanical cleansing, tendons were sutured with silk and, except in 5 cases, the wounds were sutured primarily and dressed with an immobilization dressing. The sutured wounds healed by primary intention in every case, and the crushed and contused wounds which could not be sutured healed without any evidence of infection. Evidence of a foreign body reaction from the implanted drug did not develop in any wound. During the same period two traumatic wounds, one in which there was a severed tendon, were treated in the same way but without sulfathiazole. One of these became infected and had to be opened and allowed to heal by secondary intention.

#### USE IN INFECTIONS

In 57 local infections, abscesses, carbuncles, felons and similar lesions we have implanted the microcrystalline sulfathiazole, usually in the powder form. In these wounds it was easier to compare the use of the ordinary powder with the microcrystalline form. In some cases these two preparations were used at alternate dressings and applied in the same way. When dressed on the third or fourth day after implantation of the drug there was definitely more clumping of the ordinary powder than of the crystalline form. However, it must be admitted that in several cases in which the ordinary powdered drug was used with wet saline dressings there was no evidence of caking when the dressings were removed.

The critical result to be expected from the local use of sulfathiazole is marked by the rapid and almost complete subsidence of the suppurative process. The infections were incised, pus was evacuated and the abscess cavity was dusted with the microcrystals followed by gauze packing, or the cavity was packed with gauze impregnated with the suspension of microcrystals. When the packing was removed on the third or fourth day the wounds were clean and granulating with a minimum of slough. Necrosis of fascia and tendon prolonged the suppurative process in a few cases.

The cultures in 18 cases showed staphylococci and in 7 showed streptococci. The effect of the drug seemed to be equally good against these two organisms. The

drug did not seem to free the abscess cavity of the infecting organisms because they could be recovered in repeated cultures, but the organisms seemed to be avirulent, and skin grafts could be applied with a complete take in several instances.

In 5 of these cases the infection was gangrene of the toes. In each instance a local amputation with implantation of sulfathiazole powder every third day resulted in healing without spread of the infection or gangrene.

There was a noticeable absence of the edematous hypertrophic granulations frequently seen when sulfanilamide crystals are applied to a granulating surface over a period of time.

#### MICROCRYSTALLINE SULFATHIAZOLE IN BURNS

Our experience with the use of sulfathiazole in burns has been rather limited, but the results have been so striking that they are worthy of mention. The burns have been treated by excision of the burned areas and blebs and the application of powdered sulfathiazole by a powder spray. The burned areas were then covered with moist saline dressings which were moistened every three hours with a syringe. Except for the first twenty-four hours, when the pain was relieved by morphine, the burned areas were painless. The same applications were made until healing was complete. In these cases, the absence of unhealthy granulations so frequently seen with applications of sulfanilamide was noticeable. In spite of a large burned area, the blood level of sulfathiazole was never more than a trace.

#### THE INTRA-ABDOMINAL APPLICATION OF MICROCRYSTALLINE SULFATHIAZOLE IN SUSPENSION IN SALINE SOLUTION

We have introduced the suspension of microcrystals into the abdomen in 19 instances. The amounts have varied from 4 to 14 Gm. of the drug. The operations performed were exploratory laparotomy two, enterotomy one, gastric resection three, for carcinoma of the large bowel or rectum seven, for acute pancreatitis one, for appendicitis four and for intestinal fistula one.

When the suspension is introduced into the abdomen, it rapidly spreads over the surface of the intestine and omentum. It has not produced any untoward effect in any case, if the clinical course of the patient is an indication of an adverse reaction. The drug is found in the blood in measurable amounts as early as three hours after its implantation and is still demonstrable at sixty hours.

#### PRACTICAL POINTS IN THE USE OF SULFATHIAZOLE POWDER OR SUSPENSION

In wounds that are to be sutured it is well to insert the sutures before the sulfathiazole is introduced and to tie them after its application. The presence of the powder in the wound somewhat masks the anatomic structures.

In traumatic wounds, bleeding should be stopped as completely as possible before the drug is introduced.

In abscess cavities the drug should not be dumped into the wound but should be dusted over the surface in a thin layer followed by plain gauze, or the gauze may be impregnated with the powder or suspension. Petrolatum gauze should not be used. The implantation of sulfathiazole does not contraindicate the use of wet dressings and, in infections with much slough, its action seems to be enhanced by their use.

We have made no effort to sterilize either the microcrystalline powder or the suspension and have not seen an infection arise from this practice.

## - SUMMARY

Microcrystals of sulfathiazole can be prepared by crystallization of the drug as it is violently agitated by sonic vibration. The crystals so formed may be made into a saline suspension or into powder form for use in surgical lesions.

The small size of the microcrystals permits a rate of solution which appears to be more rapid than that observed with the usual sulfathiazole powder.

We believe that sulfathiazole is superior to sulfanilamide powder as a local application in traumatic wounds and infections because it is effective against a wider range of the organisms usually found and because it exerts its effective action over a longer period of time.

The results with the local use of the microsulfathiazole in 30 traumatic wounds and 57 cases of infection have been favorable. It was used in suspension in the abdomens of 19 patients with no untoward results. The tendency of the micropreparation to clump or cake is much less than with the usual preparation of sulfathiazole powder.

## TREATMENT OF INFLUENZAL MENINGITIS WITH SULFADIAZINE

## PRELIMINARY REPORT

WALLACE SAKO, MD  
CHESTER A. STEWART, MD  
AND  
JOEL FLEET, MD  
NEW ORLEANS

Recent advances in chemotherapy have opened a more hopeful outlook on the treatment of bacterial meningitis. The usual failure of influenzal meningitis to respond favorably to the sulfonamide drugs that have been employed stands in sharp contrast to numerous recoveries which have been reported following the chemotherapy of other forms of purulent meningeal infection. It is true that sulfanilamide and sulfapyridine, used either alone or in conjunction with antiserum, have produced isolated cures, but Aleman,<sup>1</sup> who has recently reviewed the literature and her clinical experience with influenzal meningitis, stated "Every form of treatment reported in the literature is discounted by those who have seen failures, and by actual statistics where a large number have been reported."

Although anti-influenzal horse and rabbit serums have improved the prognosis of influenzal meningitis, data collected from the literature do not permit us to regard these serums with enthusiasm. The efficacy of the new concentrated antibody solution remains to be determined.<sup>2</sup>

The frequent failure of serotherapy, sulfanilamide, and sulfapyridine to influence influenzal meningitis favorably led us to seek a more effective chemotherapeutic agent. Apparently this was found in sulfadiazine. This drug is reported to have a low toxicity, to be secreted readily into the cerebrospinal fluid and to undergo relatively little acetylation. Furthermore, owing to its ready absorption and slow excretion, high blood

concentrations are sustained with comparative ease.<sup>3</sup> Theoretically, these properties should make this drug particularly suitable for the treatment of purulent meningitis.

The results obtained through the use of sulfadiazine and relatively few spinal punctures in the treatment of 7 young children with influenzal meningitis at Charity Hospital during the past few months have been so gratifying that we feel it worth while to make a preliminary report at this time.

Two of the 7 patients who received sulfadiazine died. One death (of patient 7) occurred during the performance of a cistern puncture and apparently the surgical procedure rather than the meningeal infection was responsible for the fatal issue. The other death (of patient 6) occurred after premature cessation of sulfadiazine therapy and contraction of chickenpox. Of the 5 survivors who have been discharged from the hospital all have remained well without residual symptoms after a follow-up period of four months. The temperature curves of 4 of the patients who recovered are portrayed in the accompanying chart. One of the patients who died and 3 of those who recovered were treated exclusively with sulfadiazine, while the other patient who died and 2 who recovered received anti-influenzal serum in conjunction with the drug. A detailed report of these cases will now be presented.

## REPORT OF CASES

CASE 1—B. B., a 3 year old white girl weighing 37 pounds (17 Kg.), was admitted to Charity Hospital at 6 p. m. on Dec. 8, 1941. The parents stated that the child had been well except for a slight head cold for one week prior to admission. At 10 a. m. on the day of admission she had a chill which was followed by fever. Drowsiness and stupor then ensued.

The past history revealed that the patient contracted measles at the age of 1 year and a nonspecific dysentery in June 1941, from both of which she made a complete recovery.

Physical examination on admission revealed that the child was well nourished and well developed and was stuporous; she was lying quietly in bed with both legs flexed. The rectal temperature was 102.6 F., pulse rate 120 and respiratory rate 35. The ear drums appeared normal and the mastoids roentgenographically were normal. A slight nasal discharge and a mild redness of the posterior pharynx were present. The neck was rigid and Kernig's and Brudzinkski's signs were positive. Examination of the lungs disclosed dulness to percussion with increased breath sounds and crepitant rales in the right upper lobe. The heart sounds were normal. The deep reflexes were slightly increased.

A spinal tap done on admission showed a cloudy fluid. The globulin level was increased, chlorides were 750 mg. and sugar 30 mg. per hundred cubic centimeters. The cell count was 12,000, 95 per cent of which were polymorphonuclear cells. Gram-negative pleomorphic bacilli were seen on smear, which on culture proved to be *Hemophilus influenzae*. Blood culture taken at the same time was likewise positive for the influenzal bacillus. The red blood cell count was 3,950,000, hemoglobin 55 per cent (Sahli) and white blood cell count 15,000 with 90 per cent polymorphonuclear cells. The urine was normal.

Sulfadiazine was started on admission. An initial dose of 30 grains (2 Gm.) was given by stomach tube followed by a maintenance dose of 2 grains (0.13 Gm.) per pound (450 Gm.) of body weight daily divided into six equal doses and admin-

From the Department of Pediatrics of the Louisiana State University School of Medicine and Charity Hospital.

istered every four hours. This dose was continued for nine days, at which time it was reduced to  $1\frac{1}{2}$  grains (0.1 Gm) per pound of body weight daily until the drug was discontinued nineteen days after it was started. A total of 80 Gm of sulfadiazine was given.

The patient's stupor deepened into coma the day after admission. The following day she was sitting up in bed eating and feeling much better. Three days after admission the child was afebrile. Her course is indicated in the chart by the solid line. Seven days after she was started on sulfadiazine therapy the spinal fluid was clear and the culture was negative. At this time, the drug level in the spinal fluid was 11 mg per hundred cubic centimeters of free sulfadiazine, while the blood level was 17 mg per hundred cubic centimeters. Only two spinal punctures were done. Small blood transfusions were also given. The patient was discharged twenty-three days after admission. She was seen in the outpatient clinic on two occasions with no complaints and presented no evidence of residual cerebral damage, having been afebrile throughout a period of five weeks since discharge.

CASE 2—R S, a 3 year old white boy weighing 30 pounds (13.6 Kg) was admitted to the hospital on Nov 27, 1941 complaining of fever, stomach-ache and severe headache. At

Dec 1, 1941. On this date, four days after therapy was instituted, the spinal fluid culture was negative for influenzal bacilli.

Coma subsided in two days, and the patient became afebrile nine days after the drug was started. His course is indicated in the chart by the crosses and dashes. He was discharged from the hospital twenty-four days after admission.

CASE 3—C J, a 15 month old Negro boy weighing 18 pounds (8.2 Kg) was admitted to the hospital on Dec 12, 1941 with a two day history of fretfulness, restlessness, inability to sit up or walk, fever, stiffness of the neck and back and bulging of the anterior fontanel. The past history was irrelevant.

The child was malnourished, maldeveloped and anemic. A yellow purulent discharge was found in the right auditory canal. The left drum was normal. The neck was rigid and the anterior fontanel was tense and bulging. Harsh breath sounds were heard over the left side of the chest.

Spinal tap done on admission disclosed a cloudy fluid containing 2,750 cells, chiefly polymorphonuclears. Gram negative bacilli were seen on smear which on culture proved to be *Hemophilus influenzae*.

Sulfadiazine 18 grains (1.2 Gm) was given initially by stomach tube. The maintenance dose was  $1\frac{1}{2}$  grains (0.1 Gm)

\* Subsequent temperatures remained normal in all four cases

Temperature curves of 4 patients with influenzal meningitis treated with sulfadiazine

8 a. m. on the day of admission he went to bed, and his mother had not been able to arouse him up to the time of admission.

The past history was unimportant except for pertussis, which the child contracted in 1940. On physical examination the patient was fairly well nourished and well developed and was in a comatose condition. The rectal temperature was 103 F, the pulse rate 122 and the respiratory rate 20. The eyes and ears were normal and roentgenograms of the mastoids were negative. The heart and lungs showed nothing abnormal. The neck was rigid and Kernig's sign was positive.

Spinal tap on admission showed cloudy fluid under increased pressure. Globulin was increased, sugar was reduced to 35 mg per hundred cubic centimeters, the cell count was 4,700 with 98 per cent polymorphonuclear cells. Smears from the spinal fluid revealed gram-negative bacilli. Both blood and spinal fluid cultures were positive for *Hemophilus influenzae*. The red blood cell count was 4,500,000, and the white blood cell count was 14,500 with 93 per cent polymorphonuclear cells. Routine urinalysis was negative.

On admission the patient received 30 grains of sulfadiazine followed by a daily maintenance dose of 1 grain (0.065 Gm) per pound of body weight for seven days, then  $\frac{1}{2}$  grain (0.03 Gm) per pound daily for five days,  $\frac{1}{3}$  grain (0.02 Gm) per pound daily for two days and, finally,  $\frac{1}{4}$  grain (0.016 Gm) per pound of body weight daily for five days. The drug was administered by stomach tube during the comatose stage. A total of 28 Gm of sulfadiazine was given. The blood level of free drug was 138 mg per hundred cubic centimeters on

per pound of body weight daily for seven days, then 1 grain per pound daily for seven days and finally  $\frac{1}{2}$  grain per pound daily for ten days. A total of 30 Gm was administered. On December 15 the drug level in the blood was 25 mg per hundred cubic centimeters, while the spinal fluid level was 15 mg per hundred cubic centimeters.

The condition was complicated by bronchopneumonia on the left side of the chest, which was confirmed by roentgen examination. Both the meningitis and the pneumonia responded well to chemotherapy, the temperature returning to normal eight days after admission. His course is indicated in the chart by the dashes. The spinal fluid culture was negative on December 15 and again shortly before discharge on Jan 2, 1942, twenty-two days after admission.

CASE 4—C G, an 8 month old Negro boy infant weighing 18 pounds (8.2 Kg), was admitted to the hospital on Dec 2, 1941 with a fever and stiff neck of two days' duration. Examination revealed rigidity of the neck, a bulging and tense anterior fontanel and positive Kernig's sign. The spinal fluid was cloudy, containing 3,000 cells, largely polymorphonuclear. Smear and culture showed the presence of gram negative bacilli positively identified as *Hemophilus influenzae* type I.

The patient received an initial dose of 18 grains of sulfadiazine followed by a maintenance dose of 2 grains per pound of body weight daily until the drug was discontinued on Jan 1, 1942 after nineteen days of administration, at which time the white blood cell count had dropped from 15,000 to 3,700. The child received a total of 46 Gm of the drug in addition to

60 cc of intravenous anti-influenzal rabbit serum daily for the first two hospital days and 30 cc intravenously daily for the subsequent five days. Frequent small blood transfusions were also given.

The patient appeared much unimproved clinically three days after therapy was started although pursuing a febrile course until the eleventh day of admission. His course is indicated in the chart by the circles and dashes. The spinal fluid was clear on January 9, although culture was still positive for *Hemophilus influenzae*. When spinal puncture was repeated on January 20, the culture was sterile and cytology normal. The infant was discharged January 23 and has remained well for a period of sixteen weeks following discharge. The leukocyte blood count returned to normal five days after drug therapy was discontinued. Unfortunately sulfadiazine levels were not determined.

**CASE 5—B W**, a 2 year old Negro girl weighing 30 pounds (13.6 Kg), entered the hospital on Jan. 4, 1942 with a history of having had a cold for one week. On the day of admission a chill developed which was followed by fever. The mother noted that the child had been drowsy the entire day.

It became normal. She was discharged as completely recovered forty seven days after admission.

**CASE 6—M L**, a 5 month old Negro girl infant weighing 11 pounds (5 Kg), entered the hospital on Dec. 29, 1941 because of infected third degree burns of both legs and the left arm of three days' duration. She was being treated in the surgical service with continuous saline compresses. Diarrhea developed Jan. 6, 1942 which required parenteral fluids and blood transfusions. The diarrhea was checked on January 10. Since admission the patient ran a septic type of temperature ranging from 100 to 104 F rectally. On January 14 a bilateral myringotomy was done and purulent material obtained from both ears. Unfortunately this material was not cultured. On January 19 the child appeared much worse than she had previously. Three days later stiffness of the neck and a bulging fontanel were noted. The drainage from the ears had stopped by this time.

A spinal tap done on January 22 revealed a cloudy fluid containing 3,000 cells with 90 per cent polymorphonuclear cells. Numerous short gram-negative bacilli seen on smear were identified on culture as *Hemophilus influenzae*.

Summary of Available Data on Seven Patients with Influenzal Meningitis Treated with Sulfadiazine at Charity Hospital

| Patient | Age         | Weight Pounds | Sulfadiazine       |                        |            | Total Dose Grams | Free Drug Level |                        | Spinal Fluid Culture                     | Days of Temperature Elevation | Number of Spinal Taps | Comment   |
|---------|-------------|---------------|--------------------|------------------------|------------|------------------|-----------------|------------------------|--|-------------------------------|-----------------------|---|
|         |             |               | Initial Dose Grams | Grains per Pound Daily | Days Given |                  | Blood Mg/100 Cc | Spinal Fluid Mg/100 Cc |  |                               |                       |   |

| C K     | 7 mo        | 14 1/2        | 15                 | 2                      | 1          | 15               |                 |                        |  | 1                             | 4                     | 300 cc serum intravenously died during cistern tap                            |

Physical examination on admission revealed that the child was acutely ill and in stupor. A mild rigidity of the neck was the outstanding positive finding. Spinal tap gave a cloudy fluid containing 9,600 cells, predominantly granulocytes. The chloride level was 795 mg per hundred cubic centimeters, the sugar level was 54 mg per hundred cubic centimeters and smear and culture were positive for *Hemophilus influenzae*.

On admission the patient received 60 cc of anti-influenzal serum intravenously. At the same time an initial dose of 22 1/2 grains (1.5 Gm) of sulfadiazine was given, followed by a maintenance dose of 2 grains per pound of body weight daily for nineteen days and 1 gram per pound of body weight daily for one week. A total of 92 Gm of sulfadiazine was given over a period of twenty-six days. In spite of this large dose there was no evidence of depression of either the white or red blood cells which were carefully followed.

The blood level of free sulfadiazine was 25 mg per hundred cubic centimeters on January 9. The next day the drug level was 20 mg and 10 mg per hundred cubic centimeters in the blood and spinal fluid respectively. Blood levels on January 21 and January 29 were 215 and 193 mg per hundred cubic centimeters. The spinal fluid culture was negative on January 12.

The patient was much improved clinically twenty-four hours after institution of therapy. She sat up in bed and ate fairly well although she continued to have a septic type of temperature ranging from 100 to 102 F rectally until January 23 when

Sulfadiazine was promptly started with an initial dose of 11 grains (0.7 Gm), followed by a maintenance dose of 3 1/4 grains (0.25 Gm) every three hours for nine days, then 3 1/4 grains every four hours for twenty-one days. The spinal fluid sulfadiazine level on January 23 was 7.2 mg of free drug per hundred cubic centimeters. The culture at this time was still positive for influenza bacilli. On January 27 the blood level was 207 mg while the spinal fluid level was 9.7 mg per hundred cubic centimeters. The spinal fluid culture at this time was negative although the cell count was 240.

The patient was convalescing well except for the burn and a septic type of temperature ranging from 100 to 102 F. Spinal puncture done on Feb. 5, 1942 was normal both as to cells and as to culture. Sulfadiazine was inadvertently omitted on February 11 and 12, and on the following day the child contracted chickenpox. The blood and spinal fluid drug levels on February 13 were 239 mg and 195 mg per hundred cubic centimeters respectively and the cerebrospinal fluid cell count was 3,200 mostly granulocytes. From this time on in spite of intensive chemotherapy the course was rapidly downhill and the child died on February 23 fifty-six days after admission to the contagious disease service. An autopsy revealed basilar meningitis, bilateral mastoiditis and left lateral sinus thrombosis.

**CASE 7—C K**, a 7 month old white girl weighing 14 1/2 pounds (6.6 Kg) was admitted to the hospital on Dec. 28, 1941. The child presented a history of a chill followed by fever on Christmas eve. On Christmas day the patient became drowsy

and stiffness of the neck developed. Coma developed on the day of admission.

Physical examination on admission revealed that the infant was comatose and had an acutely inflamed throat, purulent right otitis media and rigidity of the neck. A consolidation in the right upper lobe was interpreted as bronchopneumonia by roentgen examination.

A spinal tap done shortly after admission disclosed cloudy fluid with *Hemophilus influenzae* on culture. The child was given an initial dose of 15 grains of sulfadiazine followed by a maintenance dose of 5 grains (0.3 Gm) every four hours. Sixty cc of anti-influenzal serum was given intravenously for three days, then 30 cc intravenously daily until the time of death. Frequent blood transfusions were also given. Since the patient continued to have a septic temperature ranging from 100 to 103 F, a cistern puncture was being done on Jan. 4, 1942, at which time the infant suddenly ceased breathing. Death was due apparently to respiratory failure. An autopsy was not done.

A summary of the essential data presented in the 7 cases is shown in the accompanying table.

#### COMMENT

Various reports have emanated from Charity Hospital reviewing the cases of influenzal meningitis. Tripoli<sup>4</sup> in 1936 stated that 20 cases of influenzal meningitis seen from 1925 to 1934 were all fatal. Aleman<sup>1</sup> in 1940 reported that from 1935 to 1939 inclusive 27 cases were treated with no recoveries. Bryan and Musser<sup>5</sup> in 1941 remarked that for the past five years there had been 57 cases of influenzal meningitis treated with two recoveries. Forty-five of these cases occurred in children under 3 years of age with one recovery, this being in an infant 11 months old which they reported in detail. This patient received intensive treatment with large doses of sulfapyridine and anti-influenzal serum, forty-eight spinal punctures, numerous blood transfusions and complement intraspinally.

These reports reveal how gloomy the outlook for influenzal meningitis may be. The superior results that were secured with sulfadiazine in our small series of 7 cases seen within the past few months at Charity Hospital are extremely gratifying. Stupor and coma disappeared within thirty-six to forty-eight hours in all instances which responded favorably, and the spinal fluid cultures became sterile in an average of five days (range three to twenty-three days<sup>7</sup>) after the institution of drug therapy.

The series is too small to permit final conclusions. Nevertheless, the dramatic response to sulfadiazine of 5 out of 7 patients under 4 years of age can hardly be attributed to chance. One fatality which occurred is unfortunate, since recovery might have ensued if cistern puncture had not been done. We feel that this fatal issue can be attributed with reasonable certainty to the surgical procedure employed. Premature cessation of drug therapy in the other fatal case is also unfortunate.

Because of its easy absorption, low toxicity, ready secretion into the cerebrospinal fluid, relatively small degree of acetylation, slow excretion, its property of remaining in the blood stream in high concentration and its superior bacteriostatic properties against the common pyogenic organisms, sulfadiazine would seem to be the drug of choice to use in purulent meningitis. Our experience lends some support to this view. All

our patients tolerated the drug well. No vomiting or nausea was encountered, and the only toxic condition referable to the drug was a moderate degree of leukopenia which developed in 1 case. Furthermore, relatively high and sustained concentrations of sulfadiazine in the blood and cerebrospinal fluid were obtained with ease. These factors combined with the observed recovery of 5 of our 7 patients indicate to us that sulfadiazine is particularly efficacious in the treatment of influenzal meningitis.

The intravenous use of the sodium salt recommended by Long and Marshall<sup>6</sup> in meningitis was not utilized in this study, since excellent absorption occurred when sulfadiazine was administered orally or by stomach tube. Theoretically, the intravenous administration would seem advisable in order to build up high blood and spinal fluid concentrations rapidly. In the future we plan to give an initial dose of sodium sulfadiazine by this route.

It is unfortunate that sulfadiazine levels in the blood and spinal fluid were not followed closely in our series of patients. It is significant, however, that the blood concentration of the free drug under maximum dosage was always above 10 mg per hundred cubic centimeters and was sometimes as high as 25 mg per hundred cubic centimeters, with an average of 20 mg. Spinal fluid concentration of the drug in the cases in which this was determined ranged from 9.7 to 15 mg per hundred cubic centimeters. We are inclined to attribute our recent success in treating influenzal meningitis chiefly to the relatively high cerebrospinal fluid levels of sulfadiazine that were obtained.

Spinal punctures and drainage were done infrequently in our series because of the prompt clinical improvement of all patients who recovered. Our experience indicates tentatively that influenzal meningitis can be treated successfully without resort to frequent spinal punctures when sulfadiazine is given in liberal amounts.

Our experience with these few cases also seems to indicate that sulfadiazine alone was just as efficacious as the combined treatment with anti-influenzal serum. Previous unfavorable experience with serum therapy leads us to presume that the important factor in the recovery of our 5 cases was the new drug.

As far as we are aware there are no reports in the literature relative to the use of sulfadiazine in influenzal meningitis.<sup>6a</sup> Long<sup>7</sup> and others<sup>8</sup> fail to recommend the new drug in the treatment of this condition owing perhaps to the recency of its introduction and to the scarcity of reported cases. Further studies by other investigators for purposes of confirming or properly evaluating our results are to be desired.

It is tentatively suggested that during the acute stage of influenzal meningitis large doses of the drug should be administered so that the blood levels are always above 10 mg per hundred cubic centimeters, the free drug, preferably 15 to 20 mg per hundred cubic centimeters, and that the spinal fluid drug level is maintained around 10 mg per hundred cubic centimeters.

meters or higher. We believe that after an apparent cure has been obtained the patient should be maintained on reduced doses of the drug for at least two additional weeks.

#### SUMMARY

Seven children under 4 years of age with influenzal meningitis have been treated at Charity Hospital in the past few months with sulfadiazine. Five of these patients have been discharged as cured and have remained well without residuals during a follow-up period of four months. Three of these recoveries occurred with drug therapy alone, while the other 2 patients received both antiserum and the drug. Two fatalities occurred in young infants 7 and 5 months old respectively, one following a cistern puncture and the other after a prolonged course complicated by severe infected burns, chickenpox and bilateral mastoiditis with left lateral sinus thrombosis.

Clinical response to sulfadiazine was most dramatic and prompt in all cases in which recovery occurred.

Very few spinal punctures and drainages were performed.

Leukopenia, which developed in 1 patient, was the only toxic condition encountered that can be attributed to the drug.<sup>9</sup>

### DIFFUSE COLLAGEN DISEASE

#### ACUTE DISSEMINATED LUPUS ERYTHEMATOSUS AND DIFFUSE SCLERODERMA

PAUL KLEMPERER, MD

ABOU D. POLLACK, MD

AND

GEORGE BAEHR, MD

NEW YORK

The thesis of Morgagni that diseases reside in certain organs of the human body has dominated pathologic anatomy and clinical investigation for centuries. Every diagnostic endeavor was directed toward establishing the fundamental organ disease. No doubt, this working hypothesis has been the cornerstone on which rests the edifice of modern medicine.

The great advance of medicine throughout the nineteenth century is essentially founded on the method of correlating observations made in the hospital ward with those at the postmortem table. This clinicopathologic concept was further advanced by the recognition of an interdependence and unity of certain organs to form organ or tissue systems. Diseases of the hemopoietic or of the reticuloendothelial system represent such an extension of the scope of organ pathology. Nevertheless one cannot justly maintain that an essential site is established in every disease. A number of acute infections and intoxications do not produce characteristic or even significant lesions in any organ. Pathologic anatomy cannot therefore make any fundamental contribution, the exact nature of these maladies will be disclosed only by investigations into etiology and the examination of functional derangements. Another difficulty with the theory of Morgagni arises from the fact

that in certain maladies, such as rheumatic fever, apparently unrelated organs are the sites of the morbid process.

Recent anatomic investigations of disseminated lupus erythematosus have offered a similar problem in that conspicuous gross and microscopic changes were observed in various organs such as the heart, kidneys and skin. The question arose as to which of these organ changes were of primary and fundamental significance—in other words, which represented the seat of the disease, in the sense of Morgagni.

For rheumatic fever it has been shown by Klinge<sup>1</sup> that the pathognomonic involvement of the joints and of the heart is initiated by a characteristic alteration of the connective tissue followed by a specific granulomatous phase, the Aschoff nodule. Subsequent detailed investigations by this author and his school have revealed that the morbid process in rheumatic fever is not limited to these sites but affects the connective tissues throughout the body.

The apparently heterogeneous organ lesions in disseminated lupus erythematosus have similarly been shown to be the result of a fundamental alteration of the collagenous tissues. These collagen alterations are in most individual observations more widespread and conspicuous than those in rheumatic fever, affecting with particular frequency the collagen framework of the heart and of small blood vessels and capillaries, especially those of the kidneys. The connective tissue of the mediastinum and of the retroperitoneal space may also be affected by the morbid process. It is reasonable, therefore, to consider these maladies as systemic diseases of the connective tissues. The justification for the concept of a systemic disease of the connective tissues depends on the actual existence of a connective tissue system.

A system is, in the biologic sense, according to definition, an assemblage of organic structures composed of similar elements and combined for the same general functions. The connective tissue proper can then justly be regarded as a system because it consists throughout the body of an association of similar cellular and fibrillar elements held together by a third component, an amorphous ground or cement substance. The colloidal nature of this ground substance has been stressed by Schade.<sup>2</sup> Obviously these elements are combined not only for the general function of support but also for other fundamental functions. Interposed between the parenchymal cells and the canalicular blood and lymph spaces of the body, the connective tissues not only serve as the site of transfer of metabolites but most actively serve the body economy in other ways, for example, by the regulation of salt and water balance. An understanding of the colloidal nature of the extracellular portion of the connective tissues is necessary to an analysis of these functions. The same knowledge is imperative for an appreciation of the responses of the connective tissues in degeneration and inflammation. Until recently, approach to these morbid processes has been almost entirely in terms of the cellular reaction within the connective tissues. However, the participation of the fibers and ground substance may occasionally overshadow the cellular reaction. For example, in some persons an injury of the connective tissue results

<sup>9</sup> The Tulane and Independent Services of Charity Hospital gave permission for inclusion of their cases in this report. From the Laboratories of the Mount Sinai Hospital, New York.

in the excessive production of collagenous fibers and ground substance known as keloid

We first became aware of the disorder of the connective tissue as a system in our studies of disseminated lupus erythematosus.<sup>3</sup> The apparent heterogeneous involvement of various organs in this disease had no logic until it became apparent that the widespread lesions were identical in that they were mere local expressions of a morbid process affecting the entire collagenous tissue system. The most prominent of these alterations is fibrinoid degeneration—a descriptive morphologic term indicating certain well defined optical and tinctorial alterations in the collagenous fibers and ground substance. The straightening and thickening of the collagen fibers, their apparent friability, their intense eosinophilia and refractibility, together with visible increase in the ground substance can be due only to a profound physicochemical aberration of the colloid state of the connective tissues.

A similar widespread alteration of collagen has also been noted in certain cases of diffuse scleroderma.<sup>4</sup> Here, however, the collagen disturbance is manifest not only as fibrinoid degeneration but also as an increase in the bulk and density of the connective tissue. On the other hand this sclerosing type of lesion has also been observed in disseminated lupus erythematosus (spleen, pericardium, retroperitoneal tissues). It is evident, then, that fibrinoid degeneration and collagen sclerosis are the morphologic expression of different phases of a disturbed colloidal collagen system.

In these two diseases morphologic alterations may in the individual case be indeed striking. But even here the changes are hardly crucial enough to account for the profound clinical debasement and death of the patient. This is even more impressive in some cases in which the characteristic morphologic indexes of a systemic collagen disturbance are discoverable only after the most minute search. How can one account for such a discrepancy? It is unlikely that other tissue alterations have been overlooked or not comprehended. In the fully developed case the morphologic signs of implication of the collagenous tissues are quite clear. The fact of total involvement of the collagen tissue system is also clear. Can we assume, therefore, that a derangement of the colloidal state of the entire collagenous system exists though it cannot consistently be revealed by our histologic methods? Such an assumption has already been made by MacCallum<sup>5</sup> in the analysis of a case of acute scleroderma occurring in an 18 year old boy. Furthermore, the spectacular clinical state observed in sclerodema adultorum (Buschke) can be accounted for only by a similar assumption. The hardening of the skin in this disease is far out of proportion to the demonstrable histologic alteration. Moreover, the clinical reversibility of the condition lends credence to the view that the alteration is due to a transient colloidal imbalance within the collagenous tissues.

With these considerations in mind, it must become quite clear that one may regard the connective tissues of the body as a whole as a well defined, widely dispersed colloidal system liable to a variety of injuries. We are concerned here only with those processes which

affect the system in its entirety. Among these are acute disseminated lupus erythematosus and certain cases of diffuse scleroderma. There are, indeed, other morbid processes which, when analyzed, are also found to affect the connective tissue system. However, to identify this system as the seat of certain diseases is by no means to identify these diseases with one another or even to relate them. This would be an unjustifiable oversimplification.

Klinge<sup>1</sup> has charted most completely the widespread involvement of the connective tissues in rheumatic fever. Here too the seat of the disease is found in the connective tissues of the body as a whole, although those of the heart exhibit the greatest disturbance. There is in rheumatic fever, as in disseminated lupus erythematosus and in diffuse scleroderma, not only widespread involvement of the connective tissues but also similar alteration of the extracellular components of these tissues—fibrinoid degeneration. However, there are such clearcut differences in the localization and evolution of the characteristic lesions in these diseases that they must be strictly separated. Thus the glomerular lesions in disseminated lupus erythematosus and in diffuse scleroderma are never seen in rheumatic fever, the vascular lesions in the latter rarely achieve such intensity as in the former diseases. Finally, and most important, the development of a specific granulomatous phase—the Aschoff nodule—occurs neither in disseminated lupus erythematosus nor in diffuse scleroderma.

Roessle<sup>6</sup> and Jaeger<sup>7</sup> have proposed that fibrinoid degeneration of collagen is a characteristic and constant morphologic feature of diseases of allergic or "pathergic" background and have proposed that such diseases (rheumatic fever, periarteritis nodosa and thromboangiitis obliterans) may be considered in a single group designated as the "rheumatische Formenkreis." Masugi and Ya-Shu,<sup>8</sup> therefore, having found fibrinoid degeneration widespread within the blood vessels in a case of diffuse scleroderma, suggested that this disease also fell into the same category. This, we believe, is both unjust and unwise. In the first place there has been no universal acceptance of the allergic nature of rheumatic fever, the prototype of the group. Secondly, although it has been shown experimentally (Gerlach,<sup>9</sup> Klinge<sup>10</sup>) that hyperergic inflammation is characterized by fibrinoid degeneration of collagen, the converse does not necessarily follow, that widespread fibrinoid degeneration always indicates a state of hypersensitivity. We know that local fibrinoid degeneration of collagen is found in a variety of states not related to hypersensitivity. It is reasonable to assume, therefore, that widespread collagen degeneration may also be the result of causes other than hypersensitivity. In fact, the predominant incidence in females of acute disseminated lupus erythematosus and diffuse scleroderma speaks against hypersensitivity as the sole mechanism.

Until now an inordinate preoccupation with immaterial cause has shut the door to an analysis of the fundamental changes within the connective tissues considered as a colloid system. The connective tissues having been established as the seat of certain diseases, it remains for the investigator to explore this system with the methods available to the biophysicist and the chemist.

WITH HISTOLOGIC REPORT BY

R C DUNN, MD

Passed Assistant Surgeon U S Public Health Service

BETHESDA MD

Endocarditis due to fungi is an exceedingly rare clinical entity. Joachim and Polayes<sup>1</sup> described a case of subacute endocarditis with systemic mycosis (moniliasis) in a drug addict and referred to another case in which autopsy revealed evidence of mycotic endocarditis. The following case, also in a drug addict, is similar in many respects to that of Joachim and Polayes and is considered worthy of reporting because of its apparent rarity, and because of its possible public health importance since these cases occurred in drug addicts.

A white man aged 49 was admitted to the United States Public Health Service Hospital on May 11, 1940 for treatment of drug addiction (heroin) which dated from 1914. His previous medical and personal history showed nothing relevant to the present report. Physical examination on admission was negative except for many missing and some artificial teeth, defective vision and hemorrhoids. Serologic tests for syphilis were reported positive on two successive examinations after admission. He received six weekly injections of bismuth beginning June 25 and two injections of arsphenamine beginning August 13. The patient had no complaints until the afternoon of August 26, at which time he suddenly became mentally confused and what appeared to be hemiplegia on the right side developed. He was then admitted to the neuropsychiatric service. He did not lose consciousness. Neurologic and psychiatric examinations revealed considerable clouding of the sensorium especially in the fields of orientation, memory, retention and recall. There was a partial nominal aphasia together with an inability to write spontaneously with retention of ability to spell and copy. There was a right lower facial weakness on voluntary innervation, deviation of the tongue to the right on protrusion and a right upper monoparesis which was more severe in the hand. The abdominal reflexes were likewise diminished on the right side and the plantar response was absent on the right. In addition the patient exhibited a moderately severe anemia and clubbing of the fingers and toes. The spleen was considerably enlarged. Examination of the heart revealed a loud apical systolic murmur transmitted to the axilla with regular rhythm and sounds of good quality. The temperature was about 38.5 C (101.5 F) for the first few weeks of the illness following this there was an afebrile period of about two weeks.

Urinalysis was essentially negative; a blood count disclosed rather severe anemia of the secondary type. Lumbar puncture yielded a clear, colorless fluid with normal pressure and normal menometric responses. Laboratory examination of the fluid revealed 80 cells of which 71 per cent were polymorphonuclear.

Protein was 0.32 Gm per liter, the reaction for sugar was negative, as were the Kahn and the Kolmer test. The colloidal gold curve was 0001100000. A recheck on the blood serum reaction revealed a 4 plus Kahn, 2 plus Kline exclusion, doubtful Kline diagnostic and positive Kolmer reaction.

The patient's aphasia disappeared almost completely after a few days and there was decided improvement in the sensorium. The other neurologic and physical conditions remained essentially the same. Lumbar puncture was repeated on September 18 and the following results were obtained: cell count 18 predominantly lymphocytes, protein 0.26 Gm per liter, sugar too low to be read, Kahn and Kolmer reactions negative, colloidal gold test 1122100000, chlorides 706 mg per hundred cubic centimeters. A roentgenogram of the chest was reported to be negative except for a slight prominence in the region of the pulmonary conus. The differential diagnosis at this time was between cerebrovascular syphilis with thrombosis of the left middle cerebral artery and embolism of the same vessels secondary to the cardiac mitral disease. Treatment consisted of iodides by mouth, bismuth, general supportive therapy, iron and liver extract.

In spite of these measures the patient grew progressively weaker and although no new local symptoms appeared and his course was almost constantly afebrile the possibility of subacute bacterial endocarditis was entertained. Blood cultures were taken on two occasions and yielded in both instances a yeastlike growth which was subsequently demonstrated to be *Candida* (*Monilia*) *parakrusei*. Culture of the spinal fluid yielded no organisms of any kind. On October 29 petechial hemorrhages were discovered in the right lower eyelid and in the right retina.

Although the patient's focal neurologic signs improved somewhat his general condition grew progressively worse. Transfusions of 500 cc of citrated whole blood were given on October 30 and November 15 without any improvement. Lumbar puncture was done again on October 23 and the spinal fluid, which was clear, showed 10 cells (90 per cent lymphocytes), protein 0.20 Gm per liter, sugar positive, chlorides 691 mg per hundred cubic centimeters and culture negative for yeast or other organisms. Repeated blood cultures, however, continued to yield the yeastlike organism. *Streptococcus viridans* was not found. A mouse inoculated intraperitoneally with a culture of the yeastlike organism died on the eleventh day, and cultures of its brain and peritoneal washings yielded the same yeastlike organism. On October 31 urinalysis revealed 3 plus albumin and occult blood. Yeast cells were seen in the urine and cultured therefrom. His blood nonprotein nitrogen at this time was 30.9 mg and sugar 95 mg per hundred cubic centimeters. Intravenous pyelography showed nothing abnormal except ptosis of both kidneys.

About this time the patient began to exhibit a septic type of temperature curve, the peaks varying from 38 to 39.5 C (100.4 to 103.1 F). The blood count, however, continued to show anemia (hemoglobin 65 per cent, red blood cells 3,430,000) and normal white count (7,000 to 9,000) with slight neutrophilic predominance (70 to 75 per cent). Iodides up to 1 drachm (4 Gm) of saturated solution of potassium iodide three times a day and 1 Gm of sodium iodide intravenously twice daily were given without effect. Sulfathiazole (1 Gm first dose followed by 0.5 Gm every four hours thereafter) was given from November 6 to November 11 inclusive. The temperature dropped but since the patient grew much weaker and the white count dropped to 2,500 this treatment was discontinued. Numerous petechiae appeared over the extremities and back and the patient gradually became semistuporous. Neurologic examination was negative except for weakness in the right lower part of the face, some spasticity of the right upper extremity and a positive Hoffman sign on the right. The deep reflexes were now depressed symmetrically throughout. On November 20 the patient was difficult to arouse but conscious and well oriented after being aroused. The breath sounds were muffled and respirations were labored. There was pitting edema of

<sup>1</sup> From the United States Public Health Service Hospital Lexington Ky, and National Institute of Health, Bethesda Md.  
<sup>2</sup> Joachim, Henry, and Polayes, S. H. Subacute Endocarditis with Systemic Mycosis (Monilia). *J. A. M. A.* 11: 20-28 (July 20) 1940.

the hands and feet (although the patient had been digitalized), and numerous rales were found throughout the right lung. The white count was 26,700 with 75 per cent polymorphonuclear leukocytes and the temperature was normal (later subnormal). The patient's condition became rapidly worse and he died about 4 p m November 22.

The clinical diagnoses were (1) drug addiction (heroin) without psychosis, (2) cardiac disease, valvular, mitral stenosis,

Fig 1—Appearance of vegetation, grossly indistinguishable from the vegetations seen in bacterial endocarditis

sis, (3) heart disease, endocarditis, subacute bacterial (?) yeast (?), (4) embolism, cerebral, multiple, due to heart disease, (5) syphilis, tertiary, latent (?), (6) perforation, septum of perichondrium and cartilage of nose, (7) pneumonia, lobular, right, (8) pericarditis with effusion, acute, due to heart disease

#### POSTMORTEM EXAMINATION

There were many areas of petechial hemorrhage into the skin, especially on the legs and hands. Some of these were pustular.

The lungs were mottled with reddish discoloration throughout, but more especially in the lower lobes. On cross section blotchy areas of moist, rather soft consolidation were seen. Blood tinged frothy fluid exuded from the cut surface. Although both lungs showed these changes, they were more pronounced and more extensive in the right lung. Histologic Report: "The moderately congested parenchyma showed many medium sized areas, often surrounding pus-filled bronchi, with alveoli distended by fibrinocellular exudate in which neutrophils predominated, lymphocytes and macrophages being present in small numbers. The latter usually contain granular brown pigment. Most of the remaining alveoli contained a few erythrocytes, little serum and few leukocytes."

The pericardium was distended with fluid. Blood aspirated from the heart yielded a yeastlike organism on culture. The pericardium was smooth and glistening throughout. The heart was not enlarged. There was some subepicardial scarring along the arterial tree and some not adjacent to the larger vessels. The musculature and valves of the right side of the heart were grossly normal. The aortic valve and the musculature of the left side of the heart were grossly normal. There was a large friable vegetative growth measuring about 3 by 3 cm attached to the mitral valve (fig 1). The valve leaflets were greatly thickened and the chordae tendineae were thickened and shortened. Histologic Report: "The mitral valve leaf was about 2 mm thick near its base, gradually becoming thicker as it extended downward parallel to the ventricular endocardium for a distance of 8 mm and here fused with mural endocardium, the two structures merging in a 10 by 15 mm fibrous scar. The scarred valve showed focal areas of necrosis

infiltrated by many macrophages and few neutrophils and lymphocytes. Some of these foci abutted on thrombosed thin walled vessels. The valve surface was covered by a thick, firmly adherent layer of fibrinocellular exudate which contained small to medium size dense clumps of spores, usually near the surface. There were a few isolated spores, some in phagocytes, some free in the fibrin. They were gram negative, 12 to 25 microns in diameter, having a moderately distinct basophilic limiting membrane and lightly basophilic structureless central area and contained one or two deeply basophilic, usually eccentric granules. The auricular endocardium adjacent to the base of the mitral valve showed fibrous thickening, was covered by a thin layer of fibrin and was infiltrated by few to many lymphocytes. The myocardium showed slight patchy interstitial lymphocyte, plasma cell and neutrophil infiltration. The epicardium showed slight patchy fibrosis."

The spleen was considerably enlarged (weight 770 Gm). The capsule was smooth but stripped with some difficulty. Toward the posterior pole and situated somewhat inferiorly there was an old organized infarct. In several other places there were more recent, rather firm, reddish, irregularly shaped infarcts of varying size and stage of organization. Histologic Report: "There was a subcapsular area, 15 mm by 10 mm, of hemorrhagic infarction with slight marginal fibroblast proliferation and collagen deposition. The red pulp showed a slight diffuse increase in numbers of medium size and large lymphoid cells, a few scattered neutrophils and macrophages, the last occasionally exhibiting erythrophagia. Follicles were medium size and their reticulum cells were swollen and had homogeneous oxyphilic cytoplasm." Histologically the bone marrow showed that "erythropoiesis and granulocytic maturation appeared moderately depressed."

The left kidney showed no gross abnormality other than rather general reddish mottling in the cortex, which possibly represented multiple minute infarcts. The right kidney contained an infarct 15 by 30 mm in its upper pole. Histologic Report: "The moderately congested parenchyma showed few small subcapsular and subcortical, triangular and stellate areas of fibrosis with tubular atrophy, glomerular fibrosis and slight lymphocyte infiltration. Many collecting and convoluted tubules contained hyaline and granular casts. Medulla contained many small, radially elongated abscesses. Both cortex and medulla showed slight patchy interstitial fibrosis, and small arteries

Fig 2—Area of softening involving the superior portion of the kidney and the adjacent lateral portion of the internal capsule

showed moderate sclerosis. In the cortex there was a 10 by 25 mm area of infarction showing moderate peripheral fibrosis. Scattered throughout this necrotic tissue there were many densely scarred foci in which atrophic tubules and fibrous glomeruli were recognizable."

The calvarium was removed and a sample of cerebrospinal fluid was aspirated and yielded the yeastlike organism on culture. The meninges were moderately distended by a turbid fluid. The pial vessels were moderately dilated.

leptomeninges were slightly opaque and adherent over the superior longitudinal sinus bilaterally. The base of the brain and the vessels of the circle of Willis were grossly normal. Coronal sections were made at intervals of 1 cm. On the left side at the level of the insula there was a yellowish necrotic area of softening measuring 20 by 8 by 15 mm (fig 2) involving the superior portion of the putamen and the adjacent lateral portion of the internal capsule. The lumens of several small branches of the middle cerebral artery in the neighborhood of the softened area were occluded and slightly distended by clotted blood, giving the appearance of antemortem thrombosis or embolism. In the region of the right parieto-occipital sulcus, just below the gray matter, there was a hemorrhagic area about 2 cm in diameter. The other regions presented no pertinent abnormalities. Histologic Report: "There were several types of lesions, the most significant being two small areas of softening in different stages of degeneration. The most recent lesion, occurring at the junction of the white matter and cortex, showed a central blood clot containing hematoidin margined by an ill defined zone of stringy fibrillary material, and moderate numbers of lymphoid and foam cells, external to this the brain showed a broad, poorly defined zone infiltrated by many hypertrophied astrocytes. Another block showed an older linear necrotic spongy area from which all nerve cells had disappeared, surrounded by a narrow zone of slightly spongy brain tissue and many hypertrophied astrocytes. Besides these areas of softening smaller lesions occurred. Many vessels showed perivascular infiltration by lymphocytes, plasma cells and few macrophages, the latter often contained a small amount of granular pigment stained green with eosin methylene blue. Near apparently occluded capillaries in brain parenchyma there were small areas of destruction in ground substance with few microglia and astrocytes. Occasionally, chiefly in the gray matter, there were sharply defined granulomatous lesions composed of about a dozen closely packed mononuclear and epithelioid cells. No definitely recognizable spores were seen."

#### MICROLOGIC REPORT

In identification of species of *Candida* the laboratory procedures followed at the National Institute of Health include a study of the colony characteristics and microscopic morphology on acid dextrose agar, deeply inoculated cornmeal agar plates, and sometimes blood agar. The character of the growth in acid dextrose broth after incubation at 37.5 C for forty-eight hours and the fermentation reactions under the conditions outlined by Martin and his associates<sup>2</sup> are also carefully observed. For the identification of the strain described here, levulose and raffinose were included in addition to the sugars used by those investigators. Langeron and Guerra's monograph<sup>3</sup> was also consulted for descriptions of species of *Candida*.

In subcultures made when the fungus was first received two types of colonies differing slightly in appearance were observed. The two types were isolated and carefully compared. They differed slightly in the amount of gas formed in dextrose and levulose fermentation tubes and in the amount of sediment deposited on the sides and at the bottom of the tube in broth cultures, but these differences were not significant.

On acid dextrose agar (modified Sabouraud's agar—dextrose 4 per cent, neopeptone 1 per cent, agar 2 per cent, pH 5.5) the fungus forms bluish white, glistening slightly raised colonies with entire margins. In acid dextrose broth incubated at 37.5 C for forty-eight hours no surface film or ring was formed. The broth was clear and a flocculent deposit settled on the sides and at the bottom of the culture tube. On blood agar plates incubated at 37.5 C for ten days colonies were gray, smooth, glistening low dome shaped, 2 to 3 mm in diameter, with entire borders. Colony characteristics of species of *Candida* on

blood agar, in our experience, have not paralleled those described by Martin and his associates.

On cornmeal agar plates yeastlike growth was not conspicuous, but the few yeastlike cells on the agar surface appeared slightly brownish under the microscope, resembling similar cells of *Candida albicans*. Hyphal growth was greatly restricted, no grossly visible zone of hyphae appearing along the streak in cornmeal agar. Microscopically the hyphae were short and profusely branched, clusters of short stubby branches being borne in some cultures. These clusters also suggested some resemblance to *C. albicans*, but unlike most strains of that species hyphal growth was greatly restricted and no chlamydospores were produced. In petrolatum sealed sugar containing broth, incubated at 37.5 C for ten days, acid and small amounts of gas were produced in dextrose and levulose, neither acid nor gas in sucrose, lactose, maltose and raffinose. The organism was not pathogenic for rabbits even in large doses. Some animals were given repeated intravenous inoculations but lesions were not apparent when the animals were killed. Sections of the heart valves of repeatedly inoculated rabbits were normal.

The characteristics of this strain of fungus, as outlined, are those of *Candida parakrusei* (*Monilia parapsilosis*).

There are slight differences between this strain and some published descriptions of the species, as well as between different published descriptions. Some strains of *C. parakrusei*, for example, produce hyphae on cornmeal agar more freely and some produce a faint ring at the surface of dextrose broth when tubes are heavily inoculated. Some discrepancies are no doubt due in part to slight differences in culture mediums and in technique of handling. The actual differences between strains and the changes which are sometimes observed in a given strain over periods of time when in laboratory culture are, however, proof of a degree of instability clearly manifested also in other species of *Candida*.

This strain has been compared with three other strains of *C. parakrusei* also isolated from drug addicts with subacute endocarditis and sent to this laboratory for study and identification. The first strain was submitted by Dr S. H. Polayes, whose report of the case has been mentioned. A final report on this case is being published.<sup>4</sup> Two strains were received from Dr Milton Helpert and Dr A. S. Weiner, one of these having been very recently isolated. These strains were essentially alike in fermentation reactions and morphology, the differences previously mentioned being too slight to suggest any need for specific separation. The Lexington strain was also compared with a strain of *C. parakrusei* furnished by Dr Rhoda Benham. That strain presented some morphologic differences which could have been due to mutations occurring during its maintenance as a stock culture. A fifth fungus isolated from subacute endocarditis, the patient in this instance also being a drug addict, was received for identification from Dr Thomas M. Peery, George Washington University School of Medicine, who will report the case. This fungus differed from *C. parakrusei* by fermenting with gas production sucrose and raffinose as well as dextrose and levulose. There were also important morphologic differences, and the organism was identified in this laboratory as *Candida guilliermondii*.

#### COMMENT

It is extremely interesting that within the past two years 5 cases of mycotic endocarditis should be recognized in drug addicts, 4 being due to *C. parakrusei* and 1 to a related fungus, *C. guilliermondii*. It is obviously more than mere coincidence that all the patients were drug addicts who took heroin intravenously. The question arises whether *C. parakrusei* is a common contaminant of heroin or of its adulterants. Joachim and Polayes reported that in their case an organism similar

<sup>4</sup> Polayes S. H. and Erwin C. W. Final Report on the Identification of the Organism of the Irregularly Reported Case of Subacute Endocarditis and Systemic Mycosis (Mycosis). J. A. M. A. 117: 135-137 (Nov. 1) 1934.

to the one isolated from blood was isolated from the container which had held the patient's heroin.

An attempt was made by one of us (C. W. E.) at the National Institute of Health to learn whether *C. parakius* is a common contaminant of heroin or its adulterants. Eleven samples of heroin were obtained from Dr. J. Walter McDonald of the Drugs Disposal Committee, Bureau of Narcotics. These samples, according to the analyses recorded on the packages, contained as adulterants sugar (specific sugar not specified), cinchona alkaloids, mannitol, starch, brucine, procaine, quinine, sucrose, procaine hydrochloride, lactose or sucrose or some combination of these. Repeated attempts to isolate *Candida* in cultures from the heroin samples failed, although cultures of several other fungi were obtained. The number of samples tested was not large, but we believe that the samples are representative as to source and adulterants, and the failure to isolate *Candida* probably indicates that it is not a common contaminant of heroin. It would seem possible that the source of the organism in these cases was a contaminated batch of heroin which was rather widely distributed among drug addicts.

Another possible source of the fungus is the patient's skin. Langeron and Guerra state that this species is frequently found on the surface of the skin, especially about the nails, without, however, causing onychia or paronychia. Castellani isolated it from sputum. Martin and his associates isolated it from the vagina, throat, sputum and skin. Since the fungus may, therefore, be present on the skin and mucous membranes, it is possible that these patients introduced the fungus into the vein by accident at the time the drug was administered by them.

The question of primary bacterial endocarditis with superimposed mycotic infection is raised by Joachim and Polayes. There is no evidence that bacterial infection played any role in our case, and the clinical picture, which so closely resembles their case, appears to be characteristic of the disease.

Of especial interest in this case are the neurologic manifestations. Clinically, these indicated a focal brain lesion and, in view of the discovery of a yeastlike organism in the blood, suggested the possibility of torulosis. Subsequent mycologic studies, however, showed that the etiologic agent did not resemble *Torula histolytica*. As Jacobson<sup>5</sup> has pointed out, this type of infection can give rise to almost any type of neurologic picture, although usually signs of meningitic involvement predominate. The spinal fluid appeared to be characteristic of mycotic infection of the central nervous system in general.<sup>6</sup> Subsequent to this patient's death, Anderson<sup>6</sup> reported a series of 4 cases of brain abscess due to fungous infection, in 2 of which the cerebrospinal fluid findings closely resembled those in this case except that the cell counts were higher. Hence it would seem that the presence of a mild increase in the cell count with diminution in the sugar content is characteristic of cerebral, particularly meningeal, fungous infections as distinguished from meningitides of bacterial origin, in which the cell count is usually much higher and polymorphonuclear leukocytes predominate in the acute stage.

As molds of various sorts are often the bane of the clinical pathologist, the first thought—we might even say accusation—was that our culture mediums had become contaminated. We feel that this source of error was definitely ruled out in our case by meticulously checking all mediums and steps in the clinical laboratory technic, but we wonder whether other cases may not have been missed by us and by other laboratory workers by discarding such cultures as contaminations.

#### SUMMARY AND CONCLUSION

The case of mycotic endocarditis in a drug addict with postmortem observations and mycologic study illustrates the necessity of taking into consideration the possibility of mycotic infections in those cases in which the clinical picture of subacute bacterial endocarditis cannot be confirmed by the demonstration of *Streptococcus viridans* in the blood stream or in an atypical neurologic condition resembling a vascular accident of obscure etiology. It should also be suspected in what may seem to be torulosis when difficulty is encountered in positively identifying the organism. In such cases, examination of the cerebrospinal fluid, with particular reference to the quantitative sugar content and the cell count, may lead to the correct diagnosis.

An unusual organism does not necessarily indicate poor laboratory technic.

#### END RESULTS IN REMOVAL OF BLADDER NECK OBSTRUCTION

HERMAN L. KRETSCHMER, M.D.

CHICAGO

In a perusal of the voluminous literature on the subject of the treatment of bladder neck obstruction, whether by suprapubic or perineal prostatectomy or by transurethral resection, one finds that all phases of the subject have been considered, and some of them in great detail, with the possible exception of a discussion of the end results. A good deal of argumentation is to be found in the present day literature relative to the pros and cons, that is, the arguments for and against resection in the treatment of bladder neck obstruction. But an equal amount of emphasis has not been placed on the essential aspect of the treatment, which is the relief of the obstruction. Relief of the obstruction results in cure, therefore, relief of the obstruction is the objective that must be attained because unless the obstruction is completely relieved, no matter which method of operation is employed, one fails to cure the patient. On the other hand, when the obstruction has been completely removed a cure automatically follows.

I know of no more critical way of evaluating the end result than to determine whether or not the patient still has residual urine. It is to be remembered that a small amount of residual urine may be present at the time the patient leaves the hospital. I am sure that every urologist has seen these small amounts disappear without further treatment. However, one should not blind oneself to the fact that the residual urine may disappear, especially if it is more than a small amount, and that another resection is in order. With more experience the need for a second resection becomes less frequent except in the very large prostates where obviously obstructing tissue cannot all be re-

at one sitting I have seen 2 and 3 ounces of residual urine disappear. On the other hand, if it does not disappear I think the patient should have a second resection especially if symptoms persist and the urine remains turbid. In my experience, when the obstruction has been completely removed the symptoms for which the resection was done disappear and the urine gradually becomes clear. Local treatment is rarely indicated. What should be remembered is that the prostatic bed after resection does not heal readily and that in some cases the healing process is prolonged. I have examined a few patients some twelve weeks after resection and have found that healing was not complete.

In an occasional case the symptoms may persist because of an associated prostatitis, that is infection in the prostatic bed. More frequently, however, they are due to a preceding infection in the seminal vesicles. These conditions call for the usual form of treatment.

This paper is based on a study of examinations made in an unselected series of 144 cases in order to determine whether residual urine was present. In the accompany-

ing table the results obtained are presented. The results obtained in studies already published<sup>1</sup> are also included. A review of the charts shows several interesting facts.

1. A gradual definite increase in the number of patients who had no residual urine, that is, from 66.3 per cent in the first series up to 78.47 per cent in the third series of cases studied.

2. A reduction in the percentages of those having 11 to 20 cc of residual urine from 16.11 per cent in the first series to 13.88 per cent in the third series.

3. A definite increase in the sum total of these two groups, namely 82.41 per cent in the first series, 87.90 per cent in the second series and 92.36 per cent in the third series.

4. A pronounced reduction in the patients who had from 21 to 30 cc, namely 6.22 per cent in the first series, 6.95 per cent in the second series and 2.77 per cent in the third series.

5. A decided reduction in the patients who had from 31 to 40 cc, namely from 1.83 per cent in the first series to 0.694 per cent in this series.

6. A reduction in the patients who had 41 to 50 cc, namely from 2.19 per cent to 0.694 per cent.

7. A definite reduction in the patients with more than 50 cc, from 7.32 per cent in the first series to 3.47 per cent in the present series.

## Clinical Notes, Suggestions and New Instruments

### TRAUMATIC RUPTURE OF THE THORACIC DUCT WITH CHYLOTHORAX

A BRIEF REVIEW OF THE LITERATURE

JOSEPH F. DORSEY, M.D. AND GEORGE E. MORRIS, M.D.  
BOSTON

Traumatic rupture of the thoracic duct with chylous effusion into the pleural cavity is a condition so rare that the reporting of an additional case seems warranted.

The first authentic case of traumatic chylothorax was reported in 1875 by Quincke.<sup>1</sup> In 1933 Mouchet<sup>2</sup> collected 43 published reports of authentic cases and in 1937 Bauersfeld<sup>3</sup> collected 5. Since his article was published 11 additional cases have been reported, 2 by Shackelford and Fisher,<sup>4</sup> 1 each by Strauss<sup>5</sup> Beatty,<sup>6</sup> Brown,<sup>7</sup> Szajna,<sup>8</sup> Fujita,<sup>9</sup> Everhart and Jacobs,<sup>10</sup> Cellan-Jones and Murphy,<sup>11</sup> Matson and Stacy<sup>12</sup> and Hoyer,<sup>13</sup> totaling 59 reported cases.

The thoracic duct originates anterior to the body of the second lumbar vertebra as the cisterna chyli. It ascends through the posterior mediastinum between the aorta and the azygos vein, emptying into the left subclavian vein at its junction with the internal jugular vein. The duct conveys the products of fat digestion in the form of lymph laden with fat, or chyle, from its site of formation in the intestine, to the blood stream at the rate of 130 to 195 cc an hour.

Chylothorax is the result of a break in the continuity of the thoracic duct due to direct or indirect trauma or from processes which obstruct or partly destroy the duct. Trauma that is insufficient to cause fractures may result in an increased intraductal pressure causing the duct to burst. The average length of time that elapses between the accident, the latent period and the onset of symptoms is four days. However, in this case, twenty-seven days intervened between the date of injury and the second admission to the hospital.

The symptoms of chylothorax are progressive dyspnea, cyanosis, shock and signs of pleural effusion. The most important clinical features are the latent period, the repeated reaccumulation of fluid within the chest after aspiration and a gradual progressive emaciation which frequently ends in death.

Chylous fluid is a milky, noncoaguable, opalescent fluid containing fat. It is alkaline in reaction and has a specific gravity of 1.012 or higher.

In cases of traumatic chylothorax, surgical intervention with ligation of the duct below the tear or an attempt to repair the rent has resulted in a mortality rate of 100 per cent. Con-

#### REPORT OF CASE

**History**—F McL, a white man aged 60, unmarried, was admitted to the First Medical Service of the Boston City Hospital Nov 12, 1937. He was in an alcoholic stupor and unable to give a reliable history.

On Oct 16, 1937, the patient had been admitted to a surgical service of this hospital. At that time he was also in an alcoholic stupor with contusions of the back and a lacerated scalp. Roentgenograms of the chest showed an incomplete fracture of the left tenth rib. The patient stated that he had fallen down a flight of stairs immediately prior to his admission to the hospital. He remained in the hospital nine days during the first six of which he had an intermittent temperature to 101.2 F. Thereafter his course was uneventful and he was discharged with a diagnosis of incomplete fracture of the left tenth rib and acute alcoholism.

**Physical Examination**—The patient was well developed and well nourished and in no apparent distress. There was an alcoholic odor to his breath.

The temperature was 97.8 F, the pulse rate 100 and the respiratory rate 20.

The head and neck were normal.

The lower half of the right side of the chest, anteriorly and posteriorly, showed absent tactile fremitus, flatness and decreased breath and voice sounds. Breath sounds were increased in the left midchest anteriorly. No rales or friction rubs were heard.

The heart was not enlarged, the sounds were of fair quality. There were no murmurs or thrills. The rhythm was regular, A<sub>1</sub> being greater than P<sub>2</sub>. There was no peripheral sclerosis. The blood pressure was 140 systolic and 90 diastolic.

The abdomen, skeleton, reflexes and extremities were all normal.

The admission laboratory report showed that the urinalyses were negative, the hemoglobin 78 per cent Sahli and the white blood count 10,850. The Hinton reaction was negative and the nonprotein nitrogen 34.

A roentgenogram of the chest taken twelve hours after admission showed fluid in the lower half of the right side of the chest. The same day, because of pain in the chest and dyspnea, a thoracentesis was done. Thirty-one hundred cc of milky fluid was removed. The fluid on standing separated into an upper creamy layer and a lower thinner portion. Four days later it was again necessary to remove the fluid, which had reaccumulated in the right side of the chest. As the needle entered the pleural cavity the fluid spurted forth, gushing with each inspiration. On this occasion 3,500 cc was withdrawn. A roentgenogram taken immediately after the removal of fluid showed only a fracture of the left tenth rib.

During the patient's stay in the hospital 18,400 cc of the fluid was removed, the indications for thoracentesis being pain in the chest, dyspnea or cyanosis. Immediate relief from these symptoms followed each withdrawal of fluid.

There was a constant loss of the products of metabolism as well as fluid in the removed chyle. A total protein of 5 mg per hundred cubic centimeters, albumin 2.4 and globulin 2.6 (ratio of 0.92), and cholesterol of 125 on November 17 fell to a total protein of 2.7 and cholesterol of 103 on November 26. The fluid removed was milky, did not coagulate, was alkaline in reaction with a specific gravity of 1.016, total protein 3.1, albumin 2.4, globulin 0.7 and fat 1.8.

The patient was placed on a low fat, high carbohydrate, high protein diet but despite this lost weight rapidly. In an endeavor to decrease the flow of chyle through the duct a pneumothorax was done. Fluids were limited by mouth but were given by hyperdermoclysis or intravenously. On November 22 he was given 1,000 cc of chyle intravenously, he also received 1,500 cc on November 26 and 1,000 cc on November 27. Despite treatment, he became extremely weak and emaciated and died suddenly November 29, his eighteenth day in the hospital.

#### AUTOPSY REPORT

The autopsy report was made by Dr Paul Crehan and revealed the following points of interest.

Surfaces of the peritoneal cavity were smooth and glistening, there was no free fluid.

When the right pleural cavity was punctured with a needle, air escaped, the diaphragm receded and the liver assumed its normal position. In the right side of the chest there was 4,900 cc of moderately thin, gray-yellow fluid. The right lung was completely collapsed. The left pleural cavity was not remarkable, there was no free fluid and the surfaces were smooth and glistening.

The pericardial cavity was not remarkable, the surfaces were smooth and glistening and there was about 35 cc of clear serous, straw colored fluid present.

The right lung weighed 370 Gm and the left 440 Gm. The right lung was a dull gray, collapsed and completely atelectatic.

The thoracic duct was carefully dissected in its entire length and freely exposed. India ink was injected slowly into the cisterna chyli, flowed up the duct and escaped into the pleural cavity through a small "puncture-like" opening in that portion of the duct lying over the upper portion of the twelfth thoracic vertebra. The ninth and tenth ribs on the left side showed evidence of recent fractures about 4 cm from the head of the ribs. No fracture or evidence of fracture of the vertebrae was found.

## Special Article

### INDISPENSABLE USE OF NARCOTICS

*[Now that the sources of supply for narcotics have been largely shut off, their use in medical practice must be confined to the absolutely indispensable. In 1931 THE JOURNAL published a series of articles entitled "The Indispensable Use of Narcotics", these articles were collected and published in book form. This material is now republished—revised, rearranged and shortened—to guide physicians in the present attempt to confine the use of narcotic drugs to an irreducible minimum.—ED.]*

#### USES AND ABUSES OF NARCOTICS

Properly speaking, cocaine is not a narcotic. Although one of the most dangerous habit forming drugs and included under the Harrison Narcotic Act, it will not be considered here. Opium and its derivatives are the only narcotic drugs to be discussed. Opium itself is a complex substance containing some twenty alkaloids, only four of which, however, are of practical importance, namely morphine, codeine, narcotine and papaverine. Morphine has four actions on which its therapeutic uses depend. 1. In small amounts it is a depressant to the pain perceiving centers of the cerebrum. 2. In somewhat larger doses it depresses the intellectual functions and thereby exerts a somnifacient effect. 3. It is a depressant to the respiratory center, in small doses lessening its response to irritation and in larger doses reducing the amount of air moved. 4. It tends to lessen glandular activity, probably affecting, to a greater or less degree, all the secretions of the body except the sweat. 5. The older writers also ascribed to it an important effect in diminishing the contractility of the unstriated involuntary muscles, especially of the intestine, but recent investigation indicates that this action may be stimulating rather than depressing peristalsis.

Narcotine, which is the next most abundant after morphine, despite its name is not narcotic. It exerts neither analgesic nor sleep producing effects.

14 Oeken. Ein Fall von Zerrissung des Ductus thoracicus infolge Brustquetschung, München med Wchnschr 55: 1182-1183 (June) 1908.

Its most important action is a stimulation of the medullary centers governing respiration. In this it is directly antagonistic to morphine.

Papaverine has a feeble narcotic action, its dominant effect being to lessen the irritability of unstriated muscle. Like narcotine, it is stimulant to the respiratory center. It has been recommended in various spasmodic conditions of the involuntary muscles, such as asthma or colic. It is a relatively feeble drug, requiring about a grain (0.065 Gm.) to produce sensible effect on a man and is present in opium in such small amount (about 0.5 to 1 per cent) that it can play only a minor part, if any, in the effect of opium.

Codeine is similar in its general actions to morphine, although much weaker. It has relatively slight action on pain perception or intellection and is much less liable to give rise to an addiction. Ordinarily opium yields from 1 to 2 per cent of codeine.

The therapeutic purposes for which opium is used may be considered under six heads: (1) locally, (2) as an analgesic, (3) as a somnifacient, (4) as a respiratory sedative, (5) as a sudorific, (6) for its effect on the intestine.

As an assuager of pain morphine stands unrivaled at present by any other drug or combination of drugs. Nevertheless it is used more frequently and in larger quantities than is necessary and often to the detriment of the patient. By the use of other anodynes the physician can often contrive to get along with surprisingly small quantities of opiates. The decision as to whether or not to use morphine in any given case should be based on three factors: the severity of the pain, its probable duration and its underlying cause. One of the most difficult problems of therapeutics that the physician has to face is the alleviation of pain in certain chronic diseases, such as arthritis or neuritis, which may be so intense as to demand an opiate and yet promises to be of such long duration that it is likely to lose its anodyne power and to present great risks of causing addiction. Physicians may, by the exercise of more thought in practicing, do much to avoid censure in relation to narcotic addiction. In this endeavor the substitution, whenever possible, of nonhabit forming drugs for morphine or other opium alkaloids is of paramount importance. When narcotics are indispensable, however, no more should be administered than is necessary to achieve the desired end. Patients requiring daily administration should be seen often by the physician, and the amount of drugs ordered or supplied should not exceed that required by the patient until seen again. The independence of administration on the part of nurses should be strictly limited to prescription, and any change in treatment should be in writing. The patient should never be informed of the nature of the drug used or of the dose administered. The patient should never be permitted to administer the drug hypodermically to himself. Use of the drug should be discontinued immediately when no longer required. If craving has resulted, close supervision and appropriate treatment should be maintained until the patient has been rendered entirely independent of the drug.

#### USE UNDER THE HARRISON NARCOTIC ACT

The Harrison Narcotic Act covers only one class of narcotic drugs: opium and its derivatives and preparations. It covers also coca leaves and derivatives and preparations of them which are not narcotics. Registration of every practitioner who uses narcotic drugs professionally is mandatory under this act. A practitioner can lawfully administer, dispense and pre-

narcotic drugs to only such patients as are under his professional care. The act does not limit specifically the quantity that may be used or the time during which their use may be continued and requires only that the dosage be consonant with proper professional practice. It places no restriction on the form in which narcotic drugs may be administered. The administration, dispensing and prescribing of narcotic drugs for the sole purpose of satisfying the cravings of an addict are not within the bounds of professional practice. It is not, however, unlawful under the act to attempt to cure narcotic addicts of their addiction even though narcotic drugs are used in the attempt. If they are so used, the dosage from day to day should be accurately recorded. A practitioner should not administer, dispense or prescribe narcotic drugs for a stranger unless it is an obvious necessity, as in the case of a severe accident.

A practitioner can lawfully administer narcotic drugs personally to his patients hypodermically, by mouth or otherwise in any form or amount with such frequency and for such period of time as may be justified by good professional practice. A practitioner is not required by law to keep a record of the narcotic drugs he administers or dispenses to a patient on whom he personally attends, although such record can do no harm if administration of such drugs is lawful, whereas its absence may prove embarrassing. The practitioner may lawfully dispense narcotic drugs personally to his patients, but a too extensive resort to dispensing may justify a suspicion that the dispenser is only catering to narcotic addicts. Under no circumstances should a greater quantity of narcotic drugs be dispensed than the minimum required by existing conditions. The quantity should not exceed the quantity necessary to provide for the patient until he is to be seen again by the practitioner. If any greater quantity is called for, it should be provided through a prescription so that the entire transaction may be a matter of record.

A prescription for narcotic drugs need not show the ailment or injury for which it is given. Every prescription, however, must contain the patient's full name and address and the prescriber's signature, address and registration number. It must be written in ink, with an indelible pencil or on a typewriter, and must bear the full signature of the prescriber. It must be dated and signed on the day on which it is written. The act does not require a practitioner to keep a record of his prescriptions for narcotic drugs. A prescription for a narcotic drug cannot lawfully be refilled unless it is for one of the so-called exempt preparations or calls for a mixture in which the narcotic content does not exceed the narcotic content allowed by law in such preparations. The person who violates any provision of the Harrison Narcotic Act is liable to fine of not more than \$2,000 or imprisonment for not more than five years or both. Failure to pay the required tax (registration fee) within the time limit prescribed by the act adds a penalty of 25 per cent to the tax when it is paid. Under the laws of some states, conviction of violation of the Harrison Narcotic Act is a ground for suspension or revocation of a license to practice medicine.

#### NARCOTICS IN THE PRACTICE OF MEDICINE

That opium or its derivatives are indicated in certain diseases and contraindicated in others nearly all will admit, but as to specific use there are many physicians whose opinions differ and the question remains in doubt.

All will agree as to the indispensability of morphine in the hopeless cases of carcinoma, regardless of the primary site. In cases of inoperable or extensive carcinoma of the uterus, prostate, bowel, tongue, stomach or breast, with or without generalized metastases, morphine is without peer and its judicious use in relieving pain constitutes one of the greatest services the physician can render. Not only is the patient relieved of pain but the euphoria that results is a blessing, and death, which otherwise might be almost intolerable, may be made easy and comfortable.

In another group of diseases, accompanied by pain and designated by colic, morphine is the drug of choice. In this group may be included the cases with biliary, renal or lead colic. Some one of the general anesthetics, as chloroform or ether, may give the desired relief but not without the necessity of maintaining a more or less complete anesthesia to obtain muscular relaxation, with the probability of a return of the pain as soon as the anesthesia is discontinued. Accompanying renal, hepatic, pulmonary or cardiac pathologic conditions may constitute a contraindication to the use of either of the mentioned anesthetics. Except in a few cases the use of morphine is considered only a palliative measure, as renal and biliary colic are essentially surgical, while the relief in lead colic will be required only for a comparatively short time.

The further discussion of the subject may best be accomplished by considering the various diseases according to the anatomic systems. Certain cardiovascular diseases, particularly those accompanied by pain, should be mentioned. Acute pericarditis, if the pain is severe, may fail to respond to any therapeutic effort short of the administration of morphine hypodermically, to be repeated as required. Perhaps the rheumatic type, in the acute plastic stage, is the form most frequently accompanied by severe pain, although any type may belong in the group.

Difference of opinion may exist as to the necessity of employing morphine in the arteriospasmotic type of angina pectoris. While it is true that most of the cases will respond to some of the vasomotor drugs, there are instances requiring one or more doses of morphine. In the coronary occlusion type of angina, whether embolic, obliterative or thrombotic, morphine becomes imperative. In this type the anginoid attacks are prone to be severe and protracted, without much, if any, expectation of relief from the vasomotor dilators.

In the pleuropulmonary group, some of the diseases and symptoms will require consideration. Although acute plastic pleurisy, either primary or secondary to pulmonary disease, with its excruciating pain and dyspnea, responds to some extent to immobilization by adhesive straps and physical therapy, too often the desired relief is obtained only by single or repeated doses of morphine.

Acute spontaneous pneumothorax, accompanied by pain and dyspnea, requires temporary relief by morphine until other therapeutic measures can be employed.

In pulmonary diseases, certain symptoms may predominate and endanger life. Pulmonary hemorrhage from any cause, particularly the massive form, accompanied by fear and anxiety, may be much relieved or benefited by a preliminary or repeated injection of morphine, this to be followed by the usual recognized therapeutic efforts depending on the underlying pathologic condition. The dyspnea of far advanced pulmonary tuberculosis may well be classed with the

hopeless cases of carcinoma, in which some relief and comfort may be had during the final days or hours. Much relief and comfort may be had in the dyspnea of primary or secondary cancer of the lung. The same is true in some cases of aneurysm compressing the trachea or a bronchus.

In the gastrointestinal group, gastric and rectal carcinoma of the inoperable and hopeless type have already been considered. The pain in gastric and duodenal ulcers, when present, will usually respond to ulcer management and does not require special analgesics. In the event of perforation, the treatment is surgical, but as a palliative measure a single or repeated hypodermic of morphine may be advantageous.

The bowel diseases, as acute enterocolitis, spastic and ulcerative colitis, diverticulitis, appendicitis and the various forms of dysentery, require their own individual form of therapy and rarely constitute a cause for special analgesics or opiates. Usually the cramps, pains and irregular bowel action in spastic colitis, on a bowel management with tincture of belladonna, will be relieved, but occasionally the cramps or a profuse diarrhea can be controlled only by doses of an opiate, preferably camphorated tincture of opium. If the diarrhea is the predominating complaint, powdered opium may give the best results, as the powder is more slowly absorbed in the intestinal tract. With the increased knowledge of the different types of dysentery there has necessarily been an improvement in the therapy. Many of the older drugs have been discarded. As in spastic colitis, when diarrhea is particularly pronounced and uncontrollable by other means, powdered opium may be of service. Rectal tenesmus, regardless of the cause, can be best controlled or relieved by rectal suppositories containing powdered opium or morphine.

Of the remaining mentioned diseases, appendicitis is surgical and often ulcerative colitis and diverticulitis also are best treated surgically. Rarely, if ever, is an opiate required or justified.

Some mention should be made of typhoid and the former practice of prescribing morphine or opium in the treatment of complicating bowel hemorrhages. As the bleeding is usually due to the ulceration of the bowel, there is always the question of accompanying or developing perforation. When morphine or opium is prescribed, the symptoms and signs may be so modified as to make the differential determination more difficult or even impossible.

While the cerebrospinal group includes a considerable number of diseases, only a small minority of them can justly claim the indispensable therapeutic use of opium or its derivatives. It is in the symptomatic treatment of the various psychoses, and in neurotic psychoneuroses, hysteria and insomnia, that the newer hypnotics are of such indispensable service. Even in the acute manias and in delirium tremens it is only after the bromides and chloral hydrate, paraldehyde and the newer hypnotics have failed that an opiate is permissible. It should be emphasized again that the employment of opium or its derivatives for their hypnotic effect alone is open to question.

As to the spinal diseases, special mention should be made of tabes dorsalis with tabetic crises and higher pains. The use of morphine to relieve these conditions should be the last resort, as dependence and morphine addiction are easily produced.

Peripheral neuritis, local or multiple, is usually secondary to some primary pathologic condition.

neuritis may be of the alcoholic or arsenical type, perhaps due to a focal infection or a compression, as in spinal caries or a cervical rib. In each individual case the therapeutic efforts should be concentrated in an effort to relieve the primary cause.

The opium or codeine treatment of diabetes mellitus has no longer been in vogue since the advent of insulin, but not infrequently there is an associated diabetic neuritis. When the pains are severe and do not subside on diabetic therapy, occasional doses preferably of codeine or even of morphine may be required.

Some narcotic preparations have been extensively employed in the treatment of coughing. Narcotics, however, are often misused in the treatment of coughing by those who fail to bear in mind the variety of causes producing coughing, diagnostic uses of coughing, the services it performs and its disadvantages and dangers. The underlying basis of the cough must be borne in mind in all rational treatment. The productive cough should not be interfered with, unless it does more harm than good. Morphine should not be used for a cough when simple means suffice, and there are available a great many other means of controlling most types of cough. The cough reflex is depressed by relatively small doses of morphine. The exact dose necessary for the relief of coughing cannot be stated because irritation of the respiratory tract gives rise to strong stimuli, and the stronger the stimuli the greater is the depression of the center necessary to abolish the reflex that such stimuli would induce. The dose necessary, therefore, varies widely and in some cases may be as little as  $\frac{1}{80}$  grain (2 mg). One should never direct that the single dose of morphine for a cough be repeated at stated intervals without regard for the varying needs of the patient from hour to hour and from day to day. The dose should always be reduced to the least amount as alleviation of the symptoms permits.

Morphine often causes dryness of the mouth and throat. It has been suggested that the apparent diminished secretion of mucus in bronchitis may be due to greater absorption of water but it seems probable that the action is central. This may be partially overcome by the simultaneous use of nauseants when they are not otherwise contraindicated, and the simultaneous use of morphine and apomorphine has been suggested. The popular Brown Mixture contains  $\frac{1}{100}$  grain (0.2 mg) of morphine in the form of camphorated tincture of opium, and  $\frac{1}{65}$  grain (1 mg) of antimony and potassium tartrate in the average dose of 4 cc (1 fluidrachm). Morphine is said to have the advantage over codeine of causing some relaxation of the bronchial muscles, which is useful when the passages are greatly obstructed by an accumulation of mucus. This advantage, however, is usually slight compared to the many advantages of codeine.

The actions of codeine resemble those of morphine in general, but they differ in certain essentials. Codeine is less actively depressant to the higher parts of the brain and to the respiratory center, and it is more actively stimulating to the cord and, with large doses, even to the respiratory center. This probably partially explains why codeine sometimes proves unsatisfactory in the treatment of coughs, and it suggests that failure can often be avoided by a careful regulation of the dose especially if it is used in connection with other measures for lessening a cough. It is almost universally admitted that codeine relieves a cough nearly as well as morphine.

#### USE OF NARCOTICS IN SURGERY

The use of habit forming drugs in surgery may be divided into three parts: (1) the preoperative and diagnostic period; (2) the operation with its preparatory and recovery phases; and (3) the care of patients with inoperable disorders, including those cases of cancer in which surgery is inadvisable. The preoperative period should properly be spoken of as the "study period." It is the time when a proper diagnosis should be made, and, although it may necessitate innumerable tests, the principal requirement is that the patient during this period be kept as uninfluenced by drugs as possible. Pain is one of the chief diagnostic signs, and, if the diagnostician is robbed of its significance through the careless and often too free use of morphine and its derivatives its aid is removed. Those who have seen patients with abdominal or intracranial disease rendered so comfortable and even drowsy that all complaints have disappeared know the danger of the premature use of drugs. Furthermore, in the presence of head injuries administration of narcotics may be actually dangerous. However, if the investigative period is indicated for the clarification of the diagnosis, it should be carried out as expeditiously as possible, for to subject a patient to continuous pain over any great period of time is a decided reflection on one's diagnostic acumen. In the excruciating pain of smooth muscle colic, as seen in patients with renal and biliary calculus, the use of morphine would seem to find full justification. In this group of disorders however, the administration of atropine and the application of heat may prove efficacious, and this therapy deserves wider usage.

It is in the field of traumatic surgery that morphine again assumes an important role, and because of its ready availability, ease of administration and relatively certain and rapid action it is almost indispensable. Here the likelihood of the manifestation of its one objectionable feature is reduced to a minimum. Military surgery would be almost impossible without morphine. In cases of severe trauma this drug not only brings the necessary relief from suffering but, if shock intervenes, constitutes one of the chief therapeutic weapons. In such conditions morphine should be given promptly in sufficient dosage to avoid frequent repetition.

Morphine, either alone or combined with other synergistic drugs, continues to be the most universally satisfactory type of preoperative medication. For this purpose in recent years some of the newer barbiturate derivatives have proved satisfactory substitutes, and their use, even when not substituted for morphine preoperatively, can result in a material saving in the quantities of opiates employed.

After an operative ordeal it is of paramount importance to reduce the discomfort of a patient to a minimum, morphine should not be spared to accomplish this end but it should not be employed indiscriminately. Frequently the patient's discomfort may be due to quite tangible conditions, such as position, an unnecessarily tight dressing or urinary or intestinal distention, these can be dealt with specifically rather than symptomatically by the injection of morphine although to follow the former course necessarily involves slightly more effort on the part of those in attendance. In the first twenty-four to seventy-two hours following many major procedures the patient should receive sufficient morphine to keep him comfortable, provided an honest effort has been made to ascertain that his discomfort cannot be corrected by some simple remedial measure. Here

again, no doubt, in certain instances, other sedatives may be substituted for morphine, but in general such substitutions, with the possible exception of codeine, prove unsatisfactory. A further contraindication to large quantities of morphine after operation is that this drug may add a degree of atony to the intestine which proves undesirable, particularly if there was a pre-existing tendency in this direction.

One should also mention the other drugs—heroin, codeine and ethylmorphine hydrochloride—which have their devotees. Ethylmorphine hydrochloride may have its uses in ophthalmology. There are instances when codeine can be substituted for morphine quite effectively, and one should always consider this possibility, particularly in view of the almost complete absence in this drug of any tendency to the production of addiction. When administered by mouth, it may be combined advantageously with some of the coal tar derivatives.

#### NARCOTICS IN OBSTETRICS AND GYNECOLOGY

Sedatives are used during pregnancy, labor and the puerperium. During pregnancy the most common indication for narcotic medicines is the prevention of abortion. Rest in bed, combined with morphine or other preparations of opium, has saved numerous pregnancies from disaster. A combination of chloral with bromides has been used, but it is not nearly as effective. When an acute abdominal condition develops during gestation or an operation is performed at this time narcotics are particularly indispensable to allay uterine action which might expel the ovum.

Certain cases of chorea gravidarum do not respond to the usual remedies, and a combination of morphine and scopolamine may have to be exhibited for temporary sedation. The same may be said of psychoses.

Pregnancy does not contraindicate the exhibition of narcotics for any purpose that demands them. Although the effect of morphine on the unborn child has been a controversial question, the consensus appears to be that the child does not suffer except from an overdosage that would endanger the mother. However, cases are on record in which, it is said, the excessive unwarranted use of morphine during pregnancy has shown effects on the child. Chloral and chloroform pass over to the fetus, but any possible deleterious action has been considered as of secondary importance during pregnancy. The barbituric acid preparations also have widespread application in pregnancy.

During labor, opium preparations are invaluable. However, the routine administration of narcotics in labor, as demanded by hysterical magazine writers and as practiced by many overenthusiastic accoucheurs, has resulted in and is yet causing numerous deaths of newborn children and also a certain number of maternal deaths. On the other hand there is a real and scientifically proved ground for the scientific administration of narcotics during labor. The process of human childbirth is commonly pronounced to be a natural, harmless function, but accoucheurs know that, while this may have been the original intention of nature the modern woman can seldom be brought through the ordeal without some physical damage to her body, that often she cannot be got through alive, and that frequently the shock to her nervous system leaves permanent injury.

Labor is often protracted, especially in primiparas, and exhaustion of the mother may delay the process so long that infection may creep in. Here a hot pack and a rectal infusion of chloral, with a hypodermic of some opium preparation, will rest the uterus as well as the

nervous system and preserve the heart and the life forces of the patient. When she awakes, the activity of the uterus is resumed with new energy and a stubborn cervix ("rigid os") often becomes supple and dilatable in the meantime.

Only in the rarest cases is the pain of the second stage bearable by a courageous woman. It is not possible to abolish all pain, but one can and should mitigate it.

Narcotics are said to lengthen the first stage of labor and to affect the child adversely if given in the second stage. Both statements are true, but only when the drugs are improperly administered. Given at the right time and in proper dosage, the child is not endangered and the mother is made more resistant to exhaustion, acidosis, shock and postpartum hemorrhage. By preserving her strength in a prolonged first stage, narcotics actually shorten the second and forestall difficulties in the third. Even the puerperium is more smooth and convalescence more rapid, and infection is less likely.

There are few occasions for the use of narcotics in the lying-in period. After-pains are almost never so severe as to require them, the barbituric acid preparations sufficing to procure sufficient relief. A combination of codeine and acetylsalicylic acid is rarely found necessary. Naturally, any complication of the puerperium that would require narcotics for its own sake must be so treated at this time. Ordinary cases of wakefulness are well handled with a barbiturate. In the sleeplessness that is an obstinate condition in cases of puerperal infection there is no drug as efficacious as morphine, and in the diarrheas of sepsis it must also be used. To rest the bowels in cases of peritonitis it affords the patient much relief.

In general, what is said of the use of morphine and its derivatives in surgery applies equally well to the practice of gynecology. For the postoperative pain and abdominal symptoms morphine is indispensable, and the narcotic often saves life by its sedative influence on the bowel. For the treatment of chronic gynecologic diseases morphine has only limited uses and should be dispensed with as much as possible with the exception of incurable cancer.

#### NARCOTICS IN LOCAL ANESTHESIA

The ideal method of performing operations on a conscious patient without mental or physical discomfort requires a balanced use of sedatives, analgesics and anesthesia. Premedication to local anesthesia aims to diminish psychic reactions and painful sensations. In minor ambulatory procedures it is not necessary, before major surgical operations the restless night, fear and anxiety not only exhaust the patient but may cause definite bodily changes. Ordinarily sedatives of the barbituric acid series are sufficient for this purpose. The most frequent causes of toxic symptoms after local anesthesia are excessive premedication, error in the concentration of the solution of local anesthetic used, inadvertent intravenous or intraspinal injection and individual hypersensitivity to cocaine, procaine hydrochloride or other local anesthesia.

#### ABUSES OF NARCOTICS AND ADDICTION

The problem of narcotic addiction merits the attention of physicians for many reasons and at this time in particular results in an enormous diversion of narcotic drugs from their field of proper employment. Narcotics may be defined as agents that have a direct relation of the central nervous system to external as well as internal conditions of the body. They

freeing the mind more or less from the thrall of the senses, and therein lies their value as well as their danger. It is the "ease and ignorance" with which one may be relieved of a great multiplicity of symptoms by means of narcotics that makes their use an ever present temptation to patient and physician alike, and it is only by patients forswearing self medication and by physicians adopting certain definite rules regarding their employment that the abuse of narcotics can be guarded against.

Thus, narcotics should never be employed to remove a diagnostically indispensable symptom. As an illustration the old and well worn warning against the use of opium in appendicitis at once comes to the mind. In a case of appendical colic, for instance, in which operation may or may not be required, the administration of an opiate may, by the comfort it gives, create the impression that the patient is getting well and obscure the fact that inflammation is setting in and perforation is threatening or has occurred, and immediate operation is required to save life. One may relieve the pain of a strangulated hernia or an intussusception by an opiate and even check the vomiting, so that it may seem that all is well when, as a matter of fact, the patient's death is commencing with necrosis of the bowel.

Nothing is easier than to remove the results of fatigue—headache, backache, nervous irritability, insomnia—by narcotics, nothing is worse unless the fatigue is due merely to temporary overexertion. When the excessive strain is habitual and the demand for the relief of its ill effects also becomes habitual and is gratified, one is driving head on to a serious wreck. A rest treatment is needed, not dope. It is unfortunate that the term "rest cure" has become so intimately associated with the famous Weir Mitchell prescription. It should be recognized that there may be all sorts and degrees of rest treatment. For instance a regular after dinner nap is one of these, and it will often do the distracted and harassed housewife or business man more good than any amount of medicine.

Formation of habit should be the ever present specter to inspire fear of prescribing narcotics in chronic or recurring ailments, unless there are malignant conditions or limited tenure of life to make the habit relatively unobjectionable. Especially should physicians, dentists, nurses and pharmacists make it their inviolable rule never to prescribe narcotics for themselves for from among these classes is recruited a large contingent of those who become afflicted with the habitual use of narcotics. Some narcotics, as opiates and alcohol, are intrinsically habit producing. They operate in creating the notorious craving, partly by being most efficient antagonists to the disagreeable after-effects produced by the agent itself, and partly by causing mental deterioration. But all narcotics are liable to be habit forming, by reason of their very efficiency in relieving symptoms and their inability really to cure any disease. Therefore, as soon as the effect of the agent wears off the original condition asserts itself, demanding relief. Whenever, therefore, a narcotic is employed it should merely be as an adjunct to the real curative treatment. It is only when cure is impossible that the narcotic habit may be a lesser evil than unrelieved suffering. In any case an extensive range of knowledge of the many available narcotics should permit a choice of the least objectionable and yet most efficient agent for the particular patient to be relieved, and opiates should be appealed to only as a means of last resort.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT H. A. CARTER Secretary

### STITT COLD ULTRAVIOLET LAMP, MODEL S, ACCEPTABLE

Manufacturer Charles Stitt, 1944 Beachwood Drive, Hollywood, Calif

The Stitt Cold Ultraviolet Lamp, Model S, is a portable unit of the general class of "cold" or low pressure ultraviolet generators, using a gas discharge at high voltage in a fused quartz tube containing low pressure mercury vapor and argon gas. Two generators are provided, one a general body applicator consisting of 6 mm quartz tubing in the form of an Archimedes spiral 50 cm long mounted in a metal reflector 8 cm in diameter, and the other an official applicator of twin bore quartz tube. The complete assembly, which includes the applicators, a 6 volt dry cell by which they may be operated when 110 volt alternating current is not available, cables, two pairs of goggles and a dispenser containing 3 yards of rayon sleeving is mounted in a portable carrying case and weighs 25 pounds. Following are data supplied by the firm.

Stitt Cold Ultraviolet Lamp Model S

**Therapeutically**—The lamp produced the following intensity of ultraviolet light between 200 and 3200 angstroms, measured by the photometer at the specified distance:

|                                      |                            |
|--------------------------------------|----------------------------|
| Body lamp on AC at 4 inches          | 2 400 microwatts per sq cm |
| Body lamp on DC at 4 inches          | 1 000 microwatts per sq cm |
| Official on AC at $\frac{1}{4}$ inch | 3 600 microwatts per sq cm |
| Official on DC at $\frac{1}{8}$ inch | 1 800 microwatts per sq cm |

The spectral distribution was measured by the ultraviolet photometer and found to be in percentage of the total energy in wavelengths less than 3,300 angstroms:

|                                   |     |
|-----------------------------------|-----|
| Between 2 000 and 2 600 angstroms | 97% |
| Between 2 600 and 3 000 angstroms | 7%  |
| Between 3 000 and 3 200 angstroms | 1%  |
| Between 3 200 and 3 300 angstroms | 1%  |

At 4 inch spacing on the body lamp, the calculated minimum perceptible erythema times from photometer measurements were fifteen seconds on alternating current and twenty-nine seconds on direct current.

The extrapolated photometer readings give the minimum perceptible erythema time for the official unit as ten seconds on alternating current and twenty seconds on direct current at  $\frac{1}{8}$  inch spacing.

Physiologic tests on untanned abdominal skin confirmed these observations within the limits of experimental observation. The results of such tests give the minimum perceptible erythema time as follows:

|  |                              |
|--|------------------------------|
| Body lamp AC at 4 inches               | 10 seconds no erythema       |
| Body lamp AC at 4 inches               | 20 seconds definite erythema |
| Body lamp DC at 4 inches               | 20 seconds no erythema       |
| Body lamp DC at 4 inches               | 30 seconds definite erythema |
| Official lamp AC at $\frac{1}{4}$ inch | 5 seconds no erythema        |
| Official lamp AC at $\frac{1}{4}$ inch | 10 seconds definite erythema |
| Official lamp DC at $\frac{1}{8}$ inch | 10 seconds no erythema       |
| Official lamp DC at $\frac{1}{8}$ inch | 20 seconds definite erythema |

**Mechanically**—The lamp appeared well designed, light in weight and it should have good durability if handled with the care usually accorded ultraviolet lamps.

**Electrically**—An electrical switch is provided by which exposures may be timed up to four and one-half minutes. Power consumption on alternating current was fourteen watts for the body lamp and thirteen watts for the official unit. During a two hour heat test no part of the lamp or transformer became unduly heated.

The direct current power consumption was eleven watts with either burner.

The dry cells are said to last twenty hours when operated continuously

The Council's investigation revealed the following

*I Official Applicator*—Erythema tests showed that the ultraviolet output of the lamp is sufficiently intense to be acceptable. A spool of tubular artificial silk ribbon is supplied, which is slipped over the applicator to prevent burning of the orifice of a cavity that is to be irradiated. It is a simple matter to slip over the applicator a fresh piece of tubing for each patient.

*II Cold Ultraviolet Hand Lamp*—Radiometric measurements were made at a distance of 24 inches (61 cm) from the front edge of the circular quartz tubing forming the burner of the hand lamp. The intensity was 36 microwatts per square centimeter, which complies with the minimum requirements for acceptability by the Council. The Council voted to accept the lamp for inclusion in its list of accepted devices.

## Council on Foods and Nutrition

THE COUNCIL ON FOODS AND NUTRITION HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT FRANKLIN C BING, Secretary

### ANNUAL MEETING OF THE COUNCIL ON FOODS AND NUTRITION

The annual meeting of the Council on Foods and Nutrition held at the Association headquarters on March 6 was attended by the following members

|                     |                     |
|---------------------|---------------------|
| Dr Franklin C Bing  | Dr Howard B Lewis   |
| Dr George R Cowgill | Dr James S McLester |
| Dr C A Elvehjem     | Dr Irvine McQuarrie |
| Dr Morris Fishbein  | Dr Tom D Spies      |
| Dr Philip C Jeans   | Dr Russell M Wilder |
| Mr Culver S Ladd    |                     |

Drs McLester and Lewis were reelected Chairman and Vice Chairman of the Council, respectively. Among the topics given consideration at the meeting, the following items may be of interest to physicians, manufacturers and others.

*Scope of the Council*—In harmony with the instructions of the Board of Trustees, the Council has been devoting its facilities more and more to the study of broad nutritional problems and for this reason has been obliged to restrict its activities in connection with the approval of the labeling, advertising and composition of individual brands of many meritorious food products. During the last year a general plan has been formulated whereby the Council continues to give consideration primarily to special purpose foods, foods intended for the feeding of infants, and foods that have been nutritionally improved by the addition of vitamins, minerals and other dietary essentials.

Attention was given to the specific problems presented by enriched flour and enriched bread. The Council has been active in the development of these improved foods and believes that it would be to the interests of the health of the people if consumers would demand such products in place of ordinary white flour and white bread. During the last year, regulations regarding the composition and labeling of enriched flour have been developed. It is expected that the Food and Drug Administration soon will announce similar regulations regarding enriched bread. There are many hundreds of millers in the country and approximately thirty thousand bakers, the difficulty of reviewing the labels and advertising of all commercial products is at once apparent. The Council decided not to undertake consideration of individual brands of bread for acceptance or to continue to give consideration to individual brands of ordinary flour or enriched flour. It was decided instead to prepare suitable statements about the nutritive value of enriched bread and enriched flour and to try to develop a method whereby members of the food industry would be able to quote, if they so desired, the opinion of the Council on the nutritional properties of these products. A committee was appointed by the Chairman to formulate appropriate statements regarding the nutritional significance of enriched flour and enriched bread.

*Problems Presented by General Advertising*—The Council is aware of the difficulties involved in the consideration of so-called

educational advertising about foods. By insisting that advertising material is reasonably accurate prior to publication, the Council believes that it is accomplishing a public service that no other organization has been able to undertake. It was emphasized, however, that on such material it should be required at all times that an explanatory statement accompany the seal whenever displayed, this statement being to the effect that the nutritional claims in the particular advertisement have been reviewed by the Council and declared acceptable. It was also decided that the Council should sponsor more reports reviewing the scientific and medical literature on some of the foods which are extensively advertised, with a view to presenting a complete and balanced discussion of the nutritional merits and limitations of these foods.

*Publications of the Council*—The book on the vitamins which was sponsored jointly by the Council on Foods and Nutrition and the Council on Pharmacy and Chemistry now is out of print. It was decided after thorough discussion that no new edition or new series of articles on vitamins should be contemplated at the present time. The Council now has under way a new series of articles on foods and nutrition which the Editor thought could be published in THE JOURNAL beginning in June or early summer. This series of articles will be collected in book form later as a Handbook of Nutrition.

The book *Accepted Foods and Their Nutritional Significance*, published at the very end of 1939, has been received with approbation. While it was decided that no new edition would be attempted at the present time, the Council is planning to issue a supplement to bring the description of accepted articles up to date.

Consideration was given also to other possible methods of bringing to the attention of physicians the newer knowledge of foods and nutrition, particularly with a view to keeping the profession informed of dietary problems under war conditions.

*Exhibits of the Council*—The popularity of last year's exhibit on nutritionally improved flour and bread has encouraged the Council to develop another exhibit which will give consideration to nutritional deficiencies, to newer methods of diagnosis of the conditions and to the principles involved in the selection of an adequate diet. The Council voted to prepare an exhibit on these subjects in cooperation with the Food and Nutrition Board of the National Research Council. The Council's Committee on Exhibits consists of Drs Spies, Wilder and McLester.

*The Conservation of Vitamins, Especially Vitamin A*—It is well known that the supply of fish liver oils as sources of vitamin A must be conserved. The Council reviewed Limitation Order L-40 issued by the War Production Board. A significant part of the vitamin A supply is used in the fortification of foods, in particular oleomargarine. The Council voted to continue to give consideration to this problem with a view to assisting the governmental agencies to conserve the supply of vitamins for well established needs.

*Mixed Vitamin Preparations*—The Council considered a report prepared by several members of the Cooperative Committee on Vitamins and concerned with the rational use of poly-vitamin mixtures. It was decided that the report with some modifications should be sent to the Council on Pharmacy and Chemistry for further consideration.

*Pantothenic Acid and Pyridoxine in Foods*—These two substances are included among the members of the vitamin B complex. Their significance in human nutrition still remains to be determined. Experimental work with animals indicates that these substances together with biotin and choline may be of great importance. Safety lies in the ingestion of a variety of natural foods, selected so as to meet the requirements of an adequate diet. There may be a real problem of providing some of the less well known vitamins in restricted diets. The Council concluded that it would be desirable to continue to give careful consideration to developments in this field, particularly because restricted diets that may be used over long periods of time may be deficient in one or more of the known ingredients of natural foods.

*Vitamin D Milk*—The Council has been requested to express an opinion about the desirability of fortification of milk with 400 U S P units of vitamin D to each quart.

contains 8 fluidounces of milk. This would mean that the child would receive in such milk a full daily allowance of vitamin D, but only a fraction of the daily requirements for calcium.

The milk would contain in each quart 1600 U S P units, and the Council has a policy of not accepting any vitamin D milk for which claims are made for more than 400 U S P units of vitamin D to the quart.

The so-called penny milk program first was tried in the schools in Chicago in June 1940. The milk is sold to school children at a price of 1 cent for each half pint. It is served between meals. The sale of this low priced milk is made possible through a three way subsidy undertaken by the federal government, the milk dealers and the producers. In order that schools may be eligible to receive such milk, it is necessary that a considerable proportion of the school children come from homes where the income is comparatively low.

In considering the question it was mentioned that 8 fluidounces of milk is not an adequate intake of milk and that unless there is a sufficient intake of calcium such as can be provided by more milk, the consumption of adequate amounts of vitamin D may be of little value. However, children consuming penny milk might and should receive additional milk at home, and the chances were that such milk would not be fortified with vitamin D. For this special type of product, therefore, the Council voted its approval of including as much as 400 U S P units of vitamin D in 8 fluidounces.

The Council also reviewed a report on newer evidence regarding the vitamin D requirements of man. One firm has made a request that the Council accept milk that has been fortified with more than 400 U S P units of vitamin D to the quart. While milk with 600 or even 800 units of vitamin D to the quart would not be detrimental, the Council still believes that 400 units of vitamin D to the quart represents reasonable fortification in the light of present knowledge. The newer evidence on the value of larger amounts of vitamin D in the prevention of dental caries is of great interest but it is not considered conclusive enough to warrant the Council changing its decision.

**Breakfast Cereal Foods**—There are many prepared breakfast foods on the market. Few of these products have been standardized by regulations promulgated by official governmental agencies. The Council, therefore, believes it can render a service by giving particular attention to these items, especially with regard to the addition of vitamins and minerals to them. It was mentioned that breakfast cereal foods are consumed to but a slight extent, so that at most a product supplies not more than about 5 per cent of the total calories, whereas a staple food such as bread may supply 17 per cent or more of the total calories. Should a manufacturer desire to improve the nutritive value of his product, however, the Council believes that it is proper to do this within reason. The Council has accepted breakfast cereal foods that can be considered as general purpose foods when they have been fortified with moderate amounts of salts of calcium, iron and thiamine. A value now has been adopted for maximum restoration of breakfast cereal foods with riboflavin. An acceptable breakfast cereal food may contain in a quantity which will also supply 100 calories as much as 75 mg of calcium, 15 mg of iron, 0.25 mg of thiamine and 0.1 mg of riboflavin. Except for calcium these figures represent approximately the maximum amounts present in an ounce of either whole wheat, oats or corn.

**Foods Fortified with Several Vitamins and for Which Broad Nutritional Claims are Made**—A number of products recently have been marketed which represent a mixture of vitamins or minerals or both with other substances of some food value. Representations made for these products usually are extremely broad. It was decided that these products as well as others which are fortified to an extent beyond that which is acceptable for general purpose foods will be considered by the Council as special purpose foods and their acceptability judged on that basis. This means briefly that in the labeling and in the advertising it will be necessary to state exactly the composition of the product and the special use for which the product is intended.

**Commercially Canned Strained and Chopped Foods**—These products largely are intended for the feeding of infants although to some extent they may be used for special diets for adults.

The number of these products has multiplied tremendously within the last year or two. Many of the mixtures that have been compounded seem to have been formulated on principles that were not at all related to nutrition. Claims for mixtures containing as many as ten or more ingredients seem to be predicated on the false assumption that babies have peculiar tastes which need to be catered to. Color and taste in foods may be items of importance to the adult, but they have no special significance to the baby. A government order restricting the use of tin for cans permits the canning of strained and chopped foods intended for infant feeding provided the manufacturer packed that same food during 1941. This for the time being would tend to prevent the increase in the number of items that are formulated, although they still can be packed in glass.

The Council took no action on this matter but believes it is desirable to emphasize to manufacturers that multiplicity of items may limit the value of the products simply because there is greater chance that some ingredient is included that some persons cannot tolerate well. The basic principles that manufacturers should follow is, first, that the food produced be safe and, second, that it conserve the original nutritional value of the product to as high a degree as possible.

The question has been asked the Council whether fortification of canned strained or chopped foods intended for the feeding of infants would be acceptable. The Council is aware of no evidence at the present time that such a procedure would be desirable. The Council concluded that fortification of canned strained or chopped foods intended for the feeding of infants was not warranted in the light of present knowledge.

**Other Topics**—There was discussion also of recent developments which indicate the desirability of including vitamins in solutions intended for parenteral feeding. Brief reports were made of studies now under way of the stability of iodine in iodized salt, a report on the nutritive value of butter, and of diets for therapeutic purposes. In the discussion of the latter topic it was emphasized once again that reducing without medical advice may be dangerous and cannot be sanctioned by the Council.

**Mixed Juices**—Fruit and vegetable juices commercially produced have been on the market for a number of years and they have a well deserved place as sources of fluid, of sugar or other substances having food value and especially of vitamin C. Recently there has been developed a number of mixtures which consist essentially of tomato juice diluted with the juice of other vegetables. In most instances these mixtures are decidedly inferior to ordinary tomato juice in vitamin C content and probably in carotene content as well. After full discussion of the problems involved, the Council adopted the decision that it could not approve of the production of mixed juices of inferior nutritional value.

**Sugar, Candy and Carbonated Beverages**—There was considerable discussion of the nutritional problems presented by these products, which as a class comprise an appreciable proportion of the average caloric intake. It was decided that the views of the Council should be made the subject of a special report to be published later.

**Saccharin as a Substitute for Sugar in Foods**—This question has come to the fore again because of restrictions on the use of sugar. Saccharin is not a food and it is excreted unchanged. Small doses appear to produce no ill effects, but larger doses such as 15 Gm daily may cause gastrointestinal disturbances. It is hardly likely that this much saccharin ever would be consumed in one day because on the basis of sweetness it would be equivalent to 1½ pounds of sugar. The Council reiterated its views that indiscriminate use of saccharin is not advisable and that its presence in any food product should be clearly indicated to consumers.

**Sorbitol as a Substitute for Sugar in Foods**—This polyhydric alcohol, formerly a rare substance is now commercially produced in considerable quantities. The compound appears to have no injurious effect on animals when given in small amounts. Evidence about its dietary value or lack of toxicity in human beings is somewhat uncertain. The Council adopted the decision that the evidence of the food value of sorbitol at present is inadequate to warrant its endorsement as a constituent of foods.

## EFFECT OF SULFONAMIDE DRUGS ON NATURAL IMMUNITY

Although the therapeutic value of sulfonamide derivatives is now generally recognized, the effects of these drugs on the normal immunologic responses of patients is still being studied. Wood and Long,<sup>1</sup> for example, demonstrated specific mouse protective antibodies in the serums of 10 out of 12 pneumonia patients who had been treated with sulfapyridine, they concluded that the drug had not inhibited normal specific antibody formation in these patients. Similar results were reported by Edwards, Kircher and Thompson,<sup>2</sup> who studied dermal reactions to homologous capsular polysaccharides in patients with pneumonia who had been treated with this drug. In contrast with these favorable results, Kneeland and Mulliken<sup>3</sup> detected specific precipitins for homologous capsular polysaccharides in but 27 per cent of their patients treated with sulfapyridine and concluded that sulfapyridine seriously diminishes normal specific antibody formation. Similar unfavorable results were reported by Bukantz and de Gara,<sup>4</sup> who demonstrated homologous type specific precipitins in but 30 per cent of their convalescent pneumonia patients who had been treated with drugs of the sulfonamide type.

In order to harmonize this conflicting evidence, Curnen and MacLeod<sup>5</sup> of the Rockefeller Institute recently made careful parallel tests of the acquired immunity of "treated" and "untreated" rabbits inoculated with nonviable pneumococcus vaccines. Groups of 20 or more carefully selected rabbits were each given intravenously a single injection of 1 cc of heat killed type I pneumococcus vaccine, corresponding to 10 cc of an eight to ten hour broth culture of the micro-organism. Approximately half of the animals had received 0.5 Gm

of sulfapyridine by stomach tube at eight to twelve hour intervals for three days prior to the vaccination. The oral therapy was continued for twenty-four to forty-eight hours after the intravenous injection. Blood drawn at daily intervals showed adequate gastrointestinal absorption of the drug. The therapy was discontinued twenty-four to thirty-six hours before immunologic tests were made.

At intervals of forty-eight, seventy-two and ninety-six hours after vaccination, both "treated" and "untreated" rabbits, together with an equal number of normal nonvaccinated controls, were tested by an intradermal injection of 0.2 cc of a 1:5000 dilution of an eight to ten hour blood broth culture of highly virulent type I pneumococci. This injection was invariably fatal for the normal controls, causing a high sustained fever (104 F or more), extensive edema, ecchymosis and necrosis at the site of injection, and an early and progressive bacteremia, with death taking place within six days. In control nonvaccinated rabbits which had received sulfapyridine, the course, severity and termination of the disease were identical with this.

One group of vaccinated animals which had not received sulfapyridine was tested at the end of forty-eight hours, at which time they showed a well developed partial postvaccination immunity. The dermal lesion was reduced in severity and the fever and bacteremia were less pronounced, both usually terminating in about two days. In but 20 per cent of these rabbits did the disease terminate fatally. Still further reductions in clinical severity were noted in a second group of rabbits tested at the end of seventy-two hours. By the end of ninety-six hours all vaccinated rabbits had acquired a practically "solid" immunity, but 1 of the 12 animals of this group showing a distinct dermal lesion and but 4 developing a slight transient fever. None of the animals of this group developed bacteremia, and there were no deaths. Tests with type II pneumococci showed that this postvaccination immunity is type specific.

Within the limits of the experimental error parallel tests of vaccinated rabbits treated with sulfapyridine gave identical results. 80 per cent protection from fatal results within forty-eight hours, a 90 per cent reduction in mortality by the end of seventy-two hours and a 100 per cent or "solid" immunity by the end of ninety-six hours. The authors conclude from the data that under the conditions of their experiment sulfapyridine exerted no demonstrable effect on the development of postvaccination pneumococcus immunity.

Serums obtained from the same rabbits were tested for the development of type specific precipitins, agglutinins and mouse protective antibodies. Serums of untreated and sulfapyridine treated rabbits were, but one exception, free from demonstrable antibodies until ninety-six hours after vaccination. Of the ninety-six hour serums obtained from 22 "untreated" rabbits 18 protected mice against 100 minimum lethal

and 17 against 1,000 minimum lethal doses of homologous living pneumococci. Only 13 of these serums contained demonstrable type specific agglutinins, and in but 2 of them were there demonstrable type specific precipitins. Practically identical percentages were obtained in the titration of the ninety-six hour post-vaccination serums from animals which had received sulfapyridine. These identical percentages in the "treated" and "untreated" groups show that the development of circulating antibodies is not influenced by previous and concurrent administration of sulfapyridine.

Of particular significance is the fact that an 80 per cent effective tissue immunity as determined by intradermal test is developed at least forty-eight hours before the appearance of demonstrable antibodies. Of the serologic tests the mouse protection titer is by far the most sensitive and the precipitin test the least reliable. Taking into account the different technics used by the earlier clinicians, their apparently contradictory evidence can be readily harmonized. Apparently sulfonamide therapy does not prevent or delay the development of an effective convalescent, type specific immunity to pneumococci. Recovery of sulfonamide treated pneumonia patients is apparently intimately associated with the development of an active immunity.

#### PERSONNEL FACTORS IN THE NATIONAL HEALTH SURVEY

The controversies over the national health survey of 1935 and 1936 seem especially warranted now that C. C. Lienau<sup>1</sup> has published a statement on the selection, training and performance of the national health survey field staff. This study shows that exceptional but not wholly successful efforts were made to secure competent enumerators and to train them for the work. The selections were unfortunately confined largely to WPA clients. Intelligence and ability tests were used in selecting the staff and, as far as possible, only persons formerly engaged in clerical work were employed. Ninety-five per cent of the enumerators had a high school or college training.

Full recognition is given to the fact that "'measurement of ability' is not the finished technic that facile present use of the term seems to imply." There was a rather careful supervision and checking of return schedules. The question of the extent to which the tests of intelligence and ability selected a force that collected accurate information is the essential element in determining the accuracy of the returns.

The paper by Lienau postulates that the qualifications of the enumerators and therefore the accuracy of the tests used in selecting them can be measured by the relative number of illnesses reported. The

application of the tests brings out some facts of great significance in judging reliability of the entire survey. For instance the number of illnesses reported per thousand households increased steadily with the age, the education and the standing in the tests of intelligence and ability. It also varied widely according to previous occupation. Real estate and insurance agents reported 847 illnesses per thousand and teachers 833, whereas trained nurses found but 556. These figures are for female enumerators only. Male teachers found 891 illnesses per thousand households and "engineers, chemists and draftsmen" 427. This comparison is "from enumerations of more or less parallel population groups, by enumerators of differing honesty and tendency toward omission or error." It is also "supposed that net underenumeration of illness characterizes the average enumerator."

It would seem that the supervisors graded the enumerators by these standards and that it is at least possible that promotion and employment depended to some degree on the number of illnesses reported. This, of course, is not the conclusion of the paper under discussion, but a range of reported illnesses "from 427 to 900 with an average of 597 per household" would seem to raise a question not only as to the accuracy of the enumerator but as to the reliability of the study. This conclusion receives support from the statement that "it seems probable that enumerators who persisted in reporting smaller than average quantities of illness per schedule would presently receive special attention from the supervisor."

#### Current Comment

##### KELLOGG FOUNDATION AIDS IN THE EMERGENCY

The accelerated educational program in medical schools has brought particularly to the student of limited means many new responsibilities. Already there has been indication that some young men who have progressed far in their medical educational career are having difficulty in financing the program in which time is not available for earning while learning. In this emergency the W. K. Kellogg Foundation has come to the rescue by offering to each one of nearly one hundred and fifty schools of medicine, dentistry, public health and nursing in this country and Canada \$10,000 a year to be used for loans to students and scholarships. The foundation is satisfied to leave the matter of scholarships entirely in the hands of the school to use whatever machinery is customary and proper for administration. Indeed, it is planned to set up loan funds so that payments on loans will be made to the school and thus provide a continuing or revolving fund. It is expected only that the scholarship shall be granted on the basis of scholastic ability char-

<sup>1</sup> Lienau, C. C. The Selection, Training and Performance of the National Health Survey Field Staff. *Am. J. Hyg.* 34: 110 (Nov.) 19-1

acter and need of the applicant in comparison with other applicants. The only restriction suggested is that the scholarship should not amount to more than \$500 to any one student in any one year. This is a real contribution to medicine in the war effort. The medical profession may well express its appreciation of the plan and its motivation.

### PURKINJE AND THE ORIGINS OF OPHTHALMOSCOPY

Ophthalmologists and medical historians credit von Helmholtz with the invention of the ophthalmoscope. According to Garrison, "ophthalmology and surgery of the eye were put on a scientific basis mainly through the labors of Helmholtz. 'Helmholtz has opened a new world to us,' exclaimed von Graefe." Castiglioni, in his *History of Medicine*, states "A new era in the history of ophthalmology began with Helmholtz's invention of the ophthalmoscope in 1850. This great invention made possible for the first time the examination of the retina during life and opened up the whole physiology and pathology of the eyegrounds." Now a recent issue of the *Archives of Ophthalmology* offers a statement by Dr. William Thau.<sup>1</sup> "From the available evidence it clearly appears that the interior and the background of the eye of both animals and man were first observed by Johannes Evangelista Purkinje, who made enormous contributions to the sciences, including medicine, and who thus far has not been equaled in the field of ophthalmologic research." Dr. Thau offers in support of this revelation the following quotation from a speech by Heidenhain<sup>2</sup> on the occasion of the centenary of Purkinje's birth:

John Evangelist Purkinje, founder of microscopic anatomy in Germany, first to elevate physiology to the rank of an independent natural science, is hardly known and rarely recalled. One of his treatises, indeed the most outstanding in the field of sense organs, was almost totally ignored. But it is obvious that Purkinje was given more to the stimulation of thought than to following up productively what he had thought out and noticed. Thus it has happened that a great number of most important facts described in his papers were forgotten, to be rediscovered by other persons after many decades. What a sensation was caused when, in the 50's, Helmholtz discovered the eye mirror on which all modern ophthalmology is based. This instrument serves to illuminate the interior of the observed eye, so that the eyeground, which ordinarily is dark, may become visible. Purkinje described for this purpose almost exactly the procedure which thirty years later Helmholtz used. Nowhere in the literature have I found an allusion to Purkinje's discovery.

Not satisfied with this evidence, Dr. Thau succeeded in gaining access to the original copy of Purkinje's thesis in Latin. The following is quoted from an English version of it:

The clearness or turbidity of the vitreous body is recognized from without on lateral illumination and inspection by determining whether the color of the pupil is normal or cloudy according to the previously mentioned methods applying to the aqueous humor and lens. But I also had a chance to see the interior of the eye where the vitreous body is located when,

wearing myopic lenses, with candle light coming from far back, I examined the eye of a dog in order to learn about the nature of the shine which often marvelously emanates from the eyes of dogs and cats. Lo! Whenever I observed the eye of the little dog from a certain direction, that light seemed to be thrown back, until I discovered that the light is reflected from the hollow surface of the lens into the eye and then returned. When the experiment was immediately repeated with human beings the same phenomenon occurred, indeed, the whole pupil lit up in a beautiful orange color. Being still uncertain about the location of the reflected light, I constructed an artificial eye, which I filled with water, either clear or turbid to some degree, and the light shining through revealed both the background and the nature of the fluid. Thus, from now on practically no membrane or liquid content of the eye will escape the properly reflected light or the scrutinizing eye, and if practitioners, spurning the painstaking inquiry of physiologists, will not disdain or fear this [method], they will find it useful in ocular diagnosis.

Further proof of the priority of Purkinje's discoveries may be found, according to Thau, in some of the older German reference books. This information does not in the least detract from the stature of Helmholtz as a scientist or from the credit due him for devising and constructing the ophthalmoscope. However, as he himself stated (Thau, p. 315):

The real discoverer is he who had the original idea. Experiments, it is true, are also necessary, but it is easier to institute those than to find the idea, and experiments can be made by any one else.

By Helmholtz's own criterion, therefore, the credit for the origin of the ophthalmoscope should go to Purkinje.

### IS LONGEVITY INHERITED?

To determine the actuarial basis of the common belief that age is determined to a large extent by heredity, Dublin and Marks<sup>1</sup> analyzed the records of some seventy thousand persons insured by the Metropolitan Life Insurance Company for whom complete and accurate data of length of life were available concerning them and their ancestors. It is concluded that this study points broadly to a positive relationship between the longevity of parents and offspring, but this holds true only when the parents were still living when the insurance was written. This raises the further question of whether longevity in these cases is really due to inheritance or to environmental conditions. Death of the parents and consequent breaking up of the home create a risk of early death that seems more than to offset any inherited factor. The greater importance of environment is further demonstrated by the fact that the maximum difference in expectation of life due to heredity at the age of 20 does not exceed three years while there has been an average gain of about five years recorded among men of the same age in the general population during this century. "Certainly, on the basis of conditions in the world today," the study concludes, "the environmentalists have distinctly the better of the argument in so far as relates to the question of longevity."

# MEDICINE AND THE WAR

*In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession*

## THE YOUNG MEDICAL OFFICER GOES TO WAR

FRANK L. APPERLY, M.D., D.Sc.  
Professor of Pathology, Medical College of Virginia  
Richmond, Va.

The recent spate of papers and lectures on the treatment of war wounds of different parts of the human body by learned specialists brings to mind the rather amusing contrast between my own pre-World War imaginings and the realities. The specialists may indeed carry on their specialties in some base hospital far behind the lines, but the world of the young regimental medical officer is a very different thing indeed. In those far off days I imagined myself rushing from wound to wound on a shell swept battlefield, splendidly doing my duty in the face of the foe. In actual fact I did or saw very little of that noble work.

The great lesson that every medical officer must know first, foremost and all the time, is that his job is to keep the fighting ranks full, i. e. to keep fit men fit, physically and mentally, and to get slightly sick or wounded men back to the ranks as quickly as possible. After that he may attend to his more humanitarian duties, to tend, comfort and evacuate the severely wounded and the permanently disabled.

The astonishingly varied nature and wide range of the medical officer's work may be partly illustrated and perhaps more interestingly explained by telling something of my own experiences, which were fairly typical and in no way unusual.

Soon after graduation I joined the British Royal Army Medical Corps in June 1915. For some days we were taught army medical drill, stretcher drill and how to ride a horse—none of which I have done since. Sixteen days after joining the army I was on a transport for active service, destination unknown. Not until we approached the strait of Gibraltar did it become pretty obvious that the Dardanelles or our bases in Egypt would see us next.

For the purposes of this article, the remainder can be divided into five periods or phases, each concerned with a different kind of medical work.

### EGYPT—AN OVERSEAS BASE

Owing to the urgency for reinforcements for Gallipoli in July 1915, many green troops had arrived in Egypt unvaccinated, un inoculated and still wearing heavy English uniforms. These men were sent to desert camps for hardening. Here the troops suffered from heat, were bored and found themselves too close to these large Eastern cities with all their evils. Medical officers soon realized that they required all their ingenuity and all their experience of men to deal with difficulties in a world with which they themselves

were unfamiliar. Light cool uniforms had to be obtained (later even these were discarded) though no general order had been given for that purpose, so that much personal work and interviews with minor officials and officers had to be done. An early discovery was that the higher the rank of the officer the more easy he was to deal with, when he realized that one was also trying to do his best and that indeed nearly all the loose talk about "brass hats" is nonsense. The only people who made difficulties were newly joined junior officers still full of self importance or perhaps trying to cover up a lack of confidence and experience. Troops had to be vaccinated, which led to trouble with battalion commanders intent on men continuing their training and practicing bayonet fighting on the eighth and ninth days when arms were sore and tempers short. This often required much diplomacy, for, although a blustering medical officer had army regulations to back him up, better results were often obtained by persuasion than by an appeal to higher-ups.

At this time Alexandria and Port Said were crammed with transports and battleships—British, Australian, French, Russian and Italian—and lusty fellows ashore for the first time in weeks mixing with the older arrivals from the desert camps. There were also men of the Indian army, giant dignified Sikhs and the terrible little kilted Ghurkas called the Indian Highlanders. Gonorrhea and a particularly virulent form of syphilis were rife. To make these cities out of bounds was next to impossible and likely to lead to trouble so the job fell on the medical officers straining their ingenuity to the utmost. Medical officers organized games, concerts, clubs and movies, for which the Y. M. C. A. provided the materials. In the cities there were also the social requirements for the men on leave to be attended to. In the camps the main medical work consisted in attending to discharging ears, measles, eye infections and dysentery, but operations—unless essential for the life or the efficiency of the soldier—were avoided on account of the difficulty of asepsis. There were also the treatment of convalescents returned to their units, and the planning and supervision of graduated training. Requiring judgment not possessed by many were the duties of the medical boards, on which we younger men often sat as junior members to pass on the fate of convalescents—men to be returned to duty, men to be invalided back to England, Australia or India, men unfitted for full service but fit for other employment. In a total war every man can be usefully employed. Before we learned wisdom many breakdowns occurred and these failures cluttered up the camps. In addition large convoys of hospital ships from Gallipoli kept discharging thousands of wounded and even more sick (especially dysentery) into Alexandria, Port Said and Cairo, where large hotels and

public buildings had been commandeered by the Medical Corps for use as hospitals. In a smaller way medical officers soon learned to utilize whatever was nearest for their purposes—buildings of all kinds for hospitals, for measles and for venereal patients.

One of my acquaintances summarized our duties thus: one third of the time preventing men getting sick, one third treating sick and wounded and one third finding out what use could be made of the partially disabled.

#### HOSPITAL SHIPS—LINES OF COMMUNICATION

The time soon came for those of us now fast becoming "old hands" to move up. Unknown to us, but suspected, a new attack was being prepared on the Turkish positions on the heights of Gallipoli. That would mean heavy casualties and therefore many hospital ships. Unfortunately instead of medical officers and nurses being allocated to their ships in Egypt and thus giving them an opportunity to convert their ex-cattle boat or ex-cargo tramp into something like a hospital ship, all were bundled into one transport and sent straight to the Greek island of Lemnos, a few short miles off the Gallipoli coast. Next day was Sunday, August 8, the day of the "big push" and the fiercest battles of the campaign. All day long we watched the heavy bombardment of the heights by the big naval guns, the burning villages and grass fires. All day long we watched the wounded pouring in from the collecting points on the beaches. Only late in the day were we allowed inshore to help or relieve the other doctors and to give them a chance to get their first rest in two or three days. My first duties were those of an orderly, carrying food, hot tea, making myself useful in any way possible. Suddenly six of us were ordered to another ship, an ex-cattle boat, supposed to carry 600 sick and wounded. Without any opportunity to make arrangements for the disposal of our patients, we arrived on board to find 1,100 patients, lying anywhere and everywhere all over all decks, men with dysentery lying alongside men with compound fractures of the femur, without beds, without operating facilities and without medical supplies except for what we carried on our persons or found in the much outdated army medical panniers. Once again we made the best use of what was nearest to hand. Temporary latrines, several scattered on each deck, were erected for the dysentery patients. Emergency measures were improvised to prevent infection of food by the innumerable flies. Army antiseptics were discarded, and wounded limbs soaked in buckets, gasoline cans or any other receptacle which could be made to contain enough sea water and fresh water, half and half. This last, which we believe we were the first to use under similar circumstances, gave excellent results and cut down sepsis. All operations, cut to the absolute minimum, were performed in a hastily improvised operating room on the hatchway. Screening nets and cloth covers were placed on all doors leading to mess rooms, against the opposition of the ship's captain, an old time skipper, who had never seen "such dam' nonsense before." Two or more determined doctors can sometimes convince even an old sea captain. Only four men were buried at sea.

Many similar voyages were made from Gallipoli to various ports—Alexandria, Port Said, Malta, Naples

and Gibraltar—where our human cargoes were discharged. Often in spite of precautions, one or more of our medical officers would also be left behind. Occasionally there were variations. Once we were called to the rescue of a torpedoed transport with fifteen hundred Australian troops on board or scattered over the water in boats, rafts or other floating matter. Rescue work, treatment of injuries, exposure and shock provided a lively day. On another occasion a sharp storm at night drove patients crowding the top deck of an overcrowded ship into whatever shelter they could find. In spite of our best efforts to locate and move everybody in a storm on a dark night and without lights (lights of course being forbidden in submarine infested waters) the next day found many badly weakened men under lifeboats and in odd corners to which they had crawled for shelter. Soon after an intolerable stench located others with terribly swollen limbs and gas gangrene. That also was a lively day. We buried more men at sea than usual on that voyage. On other voyages neither doctors nor nurses had beds and slept where they could.

#### LEMNOS—ADVANCED BASE

Several of the Greek islands were used for advance supply depots, rest camps and as hospitals for the slightly wounded or sick. Of these the chief were Lemnos, Imbros and Samothrace. With a lull in the fighting toward the end of 1915 many of us were ordered ashore to man the rest camps and hospitals. All of these were in tents, with no beds but thin mattresses spread on the ground. However interesting Lemnos might be from a legendary and historical point of view, it is a God forsaken, treeless, rocky and dusty hole to live in. A few ancient Greek villages composed of rough stone houses, windmills, and bullocks drawing primitive plows were the only signs of life. Food and water were scarce until the navy erected a huge condenser. Flies were everywhere, so that one used both hands to convey food from plate to mouth, one hand acting as a fan. The wind was violent. One soldier wrote:

Is this the soft Aegean wind  
Which Byron wrote about?  
It blows the milk (!) from out your tea,  
The laces from your boots.

(The exclamation mark is mine.) The loose soil became clouds of dust, and when the rains came it changed to feet of mud. Tent supports could not stand upright and hospital tents collapsed on patients. With an eye to the future, however, I was able to "secure" (by methods that might not bear inspection) a number of iron bars, which, driven deep into the island kept my own tent and those of my patients upright when the others were down. The sight of my snug tent did not improve the temper of a mud caked colonel, who entered with oaths bubbling from the mud around his face. Winter, without wood for fires, brought more privations. Medical work on the island was mostly concerned with small wounds, supervising the work of rest camps (where, curiously, men who had stood down like flies when the tension relaxed) and the care of the thousands of Egyptian, Greek and cooler labor employed on the "roads" and wharves. There was also the daily sick parade for "walkers," the

rounds for "stretchers" the discharge of the fit to their units and the incapacitated to Egypt or England, medical boards inspection of food water, latrines refuse, camp and lines and finally initiating and managing concerts and games. Even the selection of songs was a job. Hymns made men homesick and restless. The bawdier songs let off steam.

Finally I became a patient myself and was returned to England on the *Aquitania*, now a splendidly fitted out hospital ship with all comforts.

#### BATTALION MEDICAL OFFICER—DOVER, ENGLAND

Although at first it seemed rather a waste to send an officer with war experience to a battalion of newly raised raw recruits, the wisdom soon became apparent. Many of the bright young graduates of our medical schools then and now, considered themselves a little too good to be "only a battalion medical officer." They preferred to be with a surgical or other specialist team in a big base hospital. I can tell these bright young men right now that they will learn little either as men or as surgeons in a big base hospital. But as a battalion medical officer they will learn vast numbers of things not taught in medical school. The battalion M O should be a man of experience wise among men and something of a doctor, lawyer, father, mother, parson or priest and friend all in one. He has medical charge (and more) of young men taken from civil life, homesick and lovesick, rebellious or sullen, adventurous or timid and what not, who have to be molded into a fighting force. Not only their physical needs but their mental and spiritual needs are his business. In a civilian army bumptious young officers, full of self importance, can drive recruits nearly to rebellion. A wise medical officer who has the great advantage of direct access and responsibility to the colonel only can often by the right word at the right time, ease serious difficulties between men and officers without apparent interference or sticking his neck out. A little talk sometimes to a miserable soldier, a word here to an officer can do wonders, especially if the doctor already has the prestige of overseas service. These things do not appear in the army manuals but are important nevertheless. It does not lower the prestige of a medical officer to carry the rifle and pack of a footsore soldier on a heavy march, as I have done on many an occasion. When the men know that the doctor is their friend and dependable the morale of that battalion is high. It cannot be too strongly emphasized that the battalion doctor should be a man of self reliance (he works alone), cool calm, with professional judgment and judgment of men and, above all, common sense and humor. During this period I served with infantry, coast artillery and antiaircraft artillery, had charge of a garrison hospital ward, had the responsibility of choosing men fit for overseas, vaccinated some 10,000 men, had troubles with medical boards who persisted in sending me men utterly unfit to march or carry a pack, trained men in the use of gas masks and became a minor expert on scabies, lice, corns and gonorrhea. One of my embarrassments as a young officer was having to advise men often older in years and sin than myself, to avoid loose women and liquor or, if they could not how to use the army "antivenereal" packets. By great good fortune I discovered an ex-Salvation Army officer, persuaded the colonel to let me have him,

and installed him in charge of the prophylactic "wash-out," where he was very happy distributing literature to his "patients."

#### BASE HOSPITAL—LONDON

Toward the end of the war I was transferred to the Fifth London General Hospital (St Thomas's Hospital) in the heart of London and opposite the Houses of Parliament. In the grounds there had been built a number of large wooden wards each holding from forty to eighty-eight beds. Here we had about 1,000 military patients, almost wholly with compound fractures. One ward was given over wholly to vascular wounds, and to this ward, by special arrangement through the War Office, came all such cases from France. In charge was Major General Sir George Makins then president of the Royal College of Surgeons of England, and I had the good fortune to be his military "resident." In addition I had a small ward of my own and was a member of the Royal Flying Corps (now R A F) Medical Board for recruit officers. On certain nights it was also my duty to meet all hospital trains coming to London stations with sick or wounded from France or elsewhere and to allocate "walkers," "sitters" or "stretchers" to the various hospitals or, if they were very ill, to take them there myself. The work differed little from that in any city hospital, the only diversion being air raids. At that time London was raided on many occasions. With the lighter bombs then in use, patients in the ferro-concrete buildings of city hospitals were safe. (The heavier bombs of 1940, however, have since wrecked a large part of St Thomas's hospital.) For patients in the wooden huts, matters were different. It was therefore our immediate duty in air raids to move all the latter into the permanent buildings—beds, Thomas's splint and traction apparatus and all—no mean order. Many of these men were shell shocked and highly nervous. Our second duty therefore was to prevent any panic. Immediately or before patients were wheeled into the central halls music, songs and games were started at once by key men. One man banged out some bawdy tunes on the piano. Others sang. The louder the better. Others threw craps or dice. Hilarious party anyhow. If you listened you heard, behind all this the crash of bombs and the even more unsteady-roar of the antiaircraft 12 pounders situated in parks and vacant lots all over the city. Here indeed the medical officer was the key man. As was his behavior or bearing, so was that of the party. Under no circumstances must he be scared or at any rate show that he was. Later, perhaps, when the raid was over and the patients were back in their wards, he might feel a little shaky, but usually with civilian dead and wounded now arriving at the hospital he had to help the civilian interns and residents and had little time to show it. When that job was finished all was well—and so to bed.

#### CONCLUSION

Of experiences under fire I have not written, partly because my own experience was small and partly because much has already been written by others. I have tried to present instead those other duties in camp, hospital ship, training depot, base hospital and advanced base which have not, so far as I know, been described elsewhere, so that others perhaps might be helped by those of us who have gone before.

## COMMISSIONS FOR MEDICAL STUDENTS

1 The War Department on May 8 granted authority to corps area commanders to waive the provisions of paragraph 5, AR 140-33 and paragraph 7b, AR 605-10, for the appointment as second lieutenant, Army of the United States (Medical Administrative Corps), of physically qualified male citizens of the United States above the age of 18 years who are bona fide accepted matriculants at approved medical schools within or without the United States. Officers so appointed will not be ordered to active duty until eligible for appointment as first lieutenant, Army of the United States (Medical Corps).

2 a Appointment will be made without reference to an examining board as prescribed in paragraph 20 c, AR 140-5, and without reference to procurement objectives.

b Appointment will be made without a report of physical examination (WD AGO Form No 63). Authority is granted to waive the provisions of Section VI, AR 605-10.

c Applications and accompanying papers as prescribed in AR 605-10 (except report required by paragraph 10a (2)(b)), as amended, will be forwarded by the dean of the medical school to the commanding general of the corps area in which the school is located, together with a certified statement that the applicant is a bona fide accepted matriculant in medicine at the institution.

d Students attending schools outside the limits of the United States will be charged with the responsibility of proper notification to the deans of the respective schools in order that the applications and accompanying papers as prescribed in paragraph 2 c (above) are forwarded to the commanding general of the corps area of permanent residence of the student.

e Officers appointed under the provisions of this letter will be discharged for the convenience of the government under the following circumstances:

- (1) Discontinuance of medical education
- (2) Matriculation at an unapproved school of medicine
- (3) Failure to complete successfully the prescribed full course of medical instruction

(4) Failure to secure appointment in the Army of the United States (Medical Corps) within one year after completion of the prescribed full course of medical instruction.

f The Surgeon General will maintain adequate records to assure timely application for appointment as first lieutenant, Army of the United States (Medical Corps), and to assure that individuals are promptly reported to the Adjutant General for discharge as provided above.

3 Properly certified applicants for and qualified students at approved schools of medicine, dentistry or veterinary medicine who already hold Reserve commissions in other arms or services will not be ordered to active duty until they:

a Come within the provisions of 2 e (1), (2), (3), or (4) above, or

b Successfully complete the prescribed full course of medical instruction, in which latter event they may be appointed in the Medical Corps, Army of the United States, in the grade of first lieutenant.

4 Properly qualified students will be invited to submit applications for appointment, final approval in each case to be made by the commanding general of the corps area in which the properly qualified student maintains permanent residence. The commanding general of each corps area is granted the authority to make such appointments.

5 Notice of appointment will be in the following form:

Date

Subject Temporary Appointment

To 2d Lieut John Henry Doe, MA-AUS, A 0-0,000,000  
549 North Blank Street, New York, N Y

1 By direction of the President you are temporarily appointed and commissioned in the Army of the United States, effective this date, in the grade and section shown in address above.

Your serial number is shown after A above. You will not perform active duty under this appointment until expressly ordered to active duty by competent authority.

2 This commission will continue in force during the pleasure of the President of the United States for the time being, and for the duration of the present emergency and six months thereafter unless sooner terminated.

3 There is enclosed herewith a form for oath of office which you are requested to execute and return promptly to the agency from which it was received by you. The execution and return of the required oath of office constitute an acceptance of your appointment. No other evidence of acceptance is required.

4 This letter should be retained by you as evidence of your appointment, as no commissions will be issued during the war.

6 Each appointee will be in the Arm and Service Assignment Group. On each copy of notice of appointment except the original a notation "A & S A G" will be placed in the lower left hand corner.

10 If an appointment is declined or canceled, the record will be filed at corps area headquarters and no report made to this office or to that of the Surgeon General.

11 Department commanders will, in general conformity with this letter, submit to this office individual recommendations for appointment.

12 The letter from this office of Feb 11, 1942, AG 2101 Med-Res (1-26-42)RB-A, Subject "Commissions for Medical Students," is rescinded except paragraph 5 thereof.

By order of the Secretary of War

J A ULIO,  
Major General,  
The Adjutant General

## FEDERAL FUNDS TO ESTABLISH RESERVE OF BLOOD PLASMA

On April 11 the sum of \$292,500 was allotted from the "Emergency Fund for the President" to the U S Public Health Service to establish reserves of liquid, frozen or dry blood plasma or serum albumin for the treatment of casualties resulting from enemy action. Grants will be made to public and private hospitals located not more than 300 miles from ocean or gulf coast under regulations which have now been promulgated by the Public Health Service (*Federal Register* 7 3448 [May 9] 1942).

To be eligible for a grant, a public or private hospital located not more than 300 miles from ocean or gulf coast must have a capacity of not less than two hundred beds, exclusive of bassinets, or two or more smaller hospitals totaling two hundred beds may submit a cooperative project, one of the participating hospitals being designated as the grantee. Furthermore the hospital must be on the approved list of the American College of Surgeons and the hospital register of the American Medical Association and must have on its professional staff a physician whose qualifications are the equivalent of those required by the American Board of Pathology for its diplomates.

A grant will cover a period of not more than twelve months following the approval of the plan, or not beyond June 30, 1944, and may be used for the purchase of equipment necessary for the preparation of liquid or frozen plasma, reconditioning of minor alterations of existing quarters, necessary traveling and subsistence allowance of \$6 a day to cover a training trip, if required, of not more than one week for the physician doing the blood and plasma project. No funds made available under a grant may be used for the payment of blood plasma. Plans for a project must first be submitted to the Chief Medical Officer, Office of Civilian Defense, and must be approved by the Public Health Service.

A plan must contain information as to the number of beds in the hospital applying for a grant, classified as follows:

to use, the name and qualifications of the physician who will direct the plasma project, a description of any present blood and plasma project, the type and amount of plasma reserve which the hospital desires to prepare, the delivered price of equipment necessary to complete the existing facilities for preparing the plasma, such items to be numbered and described in accordance with the equipment inventory in "A Manual on Citrated Normal Human Blood Plasma," issued by the Office of Civilian Defense or equivalent approved substitute equipment, the cost of materials or labor, if any, needed for adapting existing quarters to the needs of the blood plasma project, and the salaries, if any, to be paid additional personnel until the plasma reserve has been prepared.

The hospital must agree to build up a plasma reserve of at least 1 unit per bed within three months after delivery of the necessary equipment. A unit of plasma is described in the regulations as that amount derived from 500 cc of citrated whole blood, consisting of about 250 cc of liquid plasma. The agreed amount of plasma reserve must be maintained for use without charge and only for the treatment of casualties caused by enemy action. The reserve must be released for use in other local hospitals for this purpose on order of the local chief of Emergency Medical Service, or for transfer within the state on order of the state chief of Emergency Medical Service, or for transfer from one state to another on the order of the regional medical officer, Office of Civilian Defense. Liquid plasma must be kept from being outdated by replacement of

older by newer plasma. Replaced units may be utilized for current needs of the hospital in the treatment of its regular patients, provided the plasma reserve shall not be allowed to fall below the stated minimum.

All plasma must be prepared in accordance with manuals of the Office of Civilian Defense, prepared by the Subcommittee on Blood Substitutes of the National Research Council. The hospital must agree to continue the project for its current need after the expiration of the federal grant and to maintain for the duration of the war the minimum stated reserve. Thereafter the reserve may be used by the hospital without restriction. A record must be kept of all blood donors, including their blood types, to expedite obtaining donors for emergencies, and any blood plasma project must at all times be subject to inspection by authorized representatives of the Surgeon General of the United States Public Health Service.

Payments will be made on a reimbursement basis for expenditures made in accordance with the approved budget, and application for reimbursement must be notarized and addressed to the Chief Medical Officer, Office of Civilian Defense. Each hospital will be required to submit periodic reports, including clinical abstracts of any untoward experiences encountered in the use of plasma for the duration of the war.

To augment the federal fund thus made available for blood and plasma projects, a supplemental estimate of appropriation has been submitted to Congress by the President, recommending an additional \$420,000 for a continuation of the program.

#### JOINT STATEMENT BY OFFICE OF CIVILIAN DEFENSE AND AMERICAN RED CROSS

To secure unity of effort and avoid duplication of facilities in meeting civilian needs arising from enemy action this statement is issued by the Office of Civilian Defense and the American National Red Cross for the guidance of defense councils and Red Cross chapters.

It is the responsibility of local defense councils to see that adequate provision is made for all services required in the event of bombing or other enemy attack. During an emergency period the commander of the Citizens' Defense Corps will exercise control over all such services.

With respect to emergency medical services and emergency feeding, housing and clothing, provision should be made in each community in conformity with the following principles:

##### EMERGENCY MEDICAL SERVICES

During bombing or other enemy attack, all services are directed from the control center in charge of the commander of the Citizens' Defense Corps. Responsibility for the care of those injured as a result of enemy action rests with the Emergency Medical Service of the Citizens' Defense Corps under the direction of the chief of the Emergency Medical Service.

Red Cross chapters assist the Emergency Medical Service by (a) recruiting and training volunteer nurses' aides, who will be utilized by the Emergency Medical Service at base and casualty hospitals, casualty stations and first aid posts, (b) furnishing lists of persons trained in first aid to be enlisted by the Emergency Medical Service as members of its stretcher teams, (c) providing dressings, bandages and supplementary equipment as the chapter may decide in consultation with the chief of Emergency Medical Service, (d) equipping and operating emergency ambulances to be assigned to the Emergency Medical Service and to serve under its direction, (e) providing supplementary transportation for walking injured and for Emergency Medical Service personnel. During the emergency period ambulances and motor units assigned to such transportation service will be under the direction of the chief of Emergency Medical Service or the transport officer. The Emergency Medical Service of the Office of Civilian Defense will not be duplicated by the Red Cross but will be utilized by the Red Cross in natural disasters.

##### EMERGENCY FEEDING, HOUSING AND CLOTHING

In the joint statement dated April 17, 1942 of the Office of Defense Health and Welfare Services and the American Red Cross it is agreed. With respect to the emergency period dur-

ing which special facilities must be made available to meet emergency needs without notice, the Federal Security Administrator will look to the local facilities and resources of the American Red Cross to provide food, clothing and temporary shelter. These services will be provided locally during an emergency period by the Red Cross under the control of the commander of the Citizens' Defense Corps in accordance with detailed plans to be worked out jointly by the commander, the Red Cross chapter and the public welfare authority.

Defense councils should avoid duplication of these facilities. Where an Emergency Food and Housing Corps has already been organized and equipped to the satisfaction of the commander of the Citizens' Defense Corps, its function should be coordinated with the functions of the public welfare authorities and the Red Cross chapter and if possible consolidated.

After the emergency period the appropriate public agencies are expected to undertake the care of civilians in accordance with plans developed in conjunction with the Office of Defense Health and Welfare Services and the Federal Security Administrator. Funds will be made available for this purpose by the federal government through the Federal Security Administrator. Local welfare agencies and Red Cross chapters should be guided in their relationships by the agreement signed on April 17, 1942 by the Office of Defense Health and Welfare Service and the American Red Cross.

All Red Cross volunteers enlisted in the emergency feeding and housing service and all other Red Cross volunteers who are to be in service during and following bombing or other enemy action, will register with the local Civilian Defense Volunteer Office. The cards of all such registrants are to be marked so as to show that these volunteers are in Red Cross service. In order to obtain necessary freedom of movement during and immediately after enemy action, Red Cross personnel certified to the commander by the chapter for emergency feeding, housing and clothing services will be furnished with identification cards issued to Citizens' Defense Corps personnel and will be authorized to wear the official armband.

This statement supersedes the joint statements of Sept. 4 and Dec. 22, 1941.

NORMAN H. DAVIS, Chairman,  
American Red Cross  
Approved May 18, 1942

JAMES M. LANDIS, Director  
Office of Civilian Defense

# ORGANIZATION SECTION

## REGISTRATION OF DIATHERMY APPARATUS ORDERED BY FEDERAL COMMUNICATIONS COMMISSION

All possessors of apparatus designed, constructed or used for generating radio frequency energy for therapeutic purposes, described generally as diathermy apparatus, must register each such device with the Federal Communications Commission in Washington, D C, by June 8, under Order No 96, promulgated by the commission on May 18. Any person who wilfully violates any provision of the order or who falsifies any information required to be furnished to the commission becomes subject to a fine of not more than \$10,000 or imprisonment for not more than ten years, or both, and any unregistered apparatus may be confiscated.

Application for registration must be on forms obtainable from the commission in Washington or from any of its field offices. Individual applications must be made for each set of diathermy apparatus to be registered, and physicians should keep this in mind when requesting application forms. The executed forms must be forwarded to the secretary of the Federal Communications Commission in Washington. On receipt of an application, if the commission finds that sufficient and reliable information has been furnished, a nontransferable certificate of registration will be issued to the applicant, which must be conspicuously affixed to the apparatus for which it is issued.

Any person or organization hereafter in any manner coming into possession of apparatus required to be registered must apply for a certificate of registration within fifteen days after obtaining such apparatus. If registered apparatus is transferred, sold, assigned, leased, lent, stolen, destroyed or otherwise removed from the possession of the registrant the commission

must, within five days, be notified of that fact and the name of recipient of the diathermy apparatus be furnished to the commission if such person is known to the registrant.

According to a news release issued by the commission, this order does not apply to persons owning sun lamps, infra red lamps or ultraviolet ray devices. It applies only to apparatus generating electromagnetic energy at any frequency between the limits of 10 kilocycles and 10,000 megacycles. Apparatus in the possession of the United States government, its offices or agents, or apparatus which is under contract of delivery to the United States government is not subject to the registration order.

This order is a wartime security measure and its promulgation follows a determination previously reached by the Office for Emergency Management, Defense Commission Board, in Order No 4, that the national security and defense and the successful conduct of the war demand that the government have knowledge of all persons who possess apparatus equipped for the transmission of radio frequency energy. Diathermy apparatus may not only interfere with radio reception but can be easily converted into short wave radio transmitters and thus may be used to furnish valuable information to the enemy.

Application forms for the registration of diathermy apparatus may be obtained from the Federal Communications Commission in Washington, D C, or from any of the field offices of the commission listed. Physicians should apply immediately to the nearest office for an application form to cover each unit of diathermy apparatus possessed.

### OFFICIAL NOTES

#### THE ATLANTIC CITY SESSION

#### Atlantic City Civic Groups Invite Physician Members

The Local Committee on Arrangements for the annual session of the American Medical Association in Atlantic City announces a meeting of the combined civic groups of Atlantic City for

visiting physicians who are members of Kiwanis, Rotary, Exchange, Reciprocity and similar organizations at Hatteras Restaurant, June 9, at 12 30 p m. Dr Perrin H Lee, Johns Hopkins University Medical School will speak on 'Medical Science in the War Effort'.

## MEDICAL LEGISLATION

### DISTRICT OF COLUMBIA

*Change in Status*—H R 6362 has passed the House, imposing an annual registration requirement on persons licensed to practice the healing art in the District of Columbia. The registration fee will be \$2.

### MEDICAL BILLS IN CONGRESS

*Change in Status*—S 2025 has passed the Senate and House of Representatives proposing to readjust the pay and allowances of personnel of the army, navy and marine corps coast guard, coast and geodetic survey and Public Health Service. When this bill was considered on the floor of the House Representative Costello, California offered an amendment to the section of the bill pertaining to the appointment of commissioned officers in the army as follows: Provided, That nothing in this section shall preclude the appointment of commissioned officers for service in the Medical Corps in the Army of the United States

made in part from among graduates of reputable schools of osteopathy, who are licensed or eligible for license under state law to practice medicine, or osteopathy, as the case may be, and who are otherwise qualified under such regulations as the President may prescribe." The proposed amendment was rejected.

*Bills Introduced*—H J Res 312, introduced by Representative Barden, North Carolina, proposes to authorize an additional appropriation of \$1,000,000 for the fiscal year of 1943 for expenditure in carrying out the provisions of an act to provide for the promotion of vocational rehabilitation of persons disabled in industry or otherwise. H R 7089, introduced by Representative Brooks, Louisiana, would direct the Secretary of War to take such action as may be necessary, and as may be possible in view of the number of registered pharmacists serving in or whose services are available to the army, to assure that a registered pharmacist is placed in charge of each army dispensary or similar establishment from which drugs are dispensed.

## WOMAN'S AUXILIARY

### Arkansas

Mrs William Hibbitts, program chairman for the Woman's Auxiliary to the American Medical Association conducted a quiz at the January meeting of the Bowie and Miller counties medical auxiliary at the home of Mrs R R Kirkpatrick. The quiz, entitled "To Be Informed" was prepared for auxiliaries to be used throughout the United States. The questions pertained to politics, public relations, the American Medical Association and its auxiliaries. For correct answers, members were awarded prizes from a "grab bag."

### Georgia

The Woman's Auxiliary to the Baldwin County Medical Society held a meeting at the home of Mrs L P Longino in Milledgeville. Mrs Richard Binion, president, presided. Col Kyle T Alfriend talked on world conditions.

The Woman's Auxiliary to the Fulton County Medical Society held its January meeting in the new Academy of Medicine in Atlanta. Mrs Murdock Eguen, president, presided. Dr Sam Guy, head of the department of chemistry at Emory University, talked on the part science is playing in the war.

The new Academy of Medicine was dedicated recently. The woman's auxiliary had charge of serving a turkey dinner to 500 guests and members, Mrs Eustace Allen, Mrs Crawford Barnett, Mrs Hal Davison and Mrs W W Anderson ably assisted by their committees having charge. Mrs Murdock Eguen, president, and various chairmen from the auxiliary, assisted the Fulton County Medical Society with the decorations and equipping of the building.

Various auxiliaries over the state observed Doctor's Day on March 30, this occasion being one on which members of the profession both living and dead are honored. A Georgia woman, Mrs C B Almand, of Winder first originated Doctor's Day, and it was first observed by her auxiliary, that of Barrow County, in 1933. In 1934 the state auxiliary adopted the idea and in 1935 through the efforts of Mrs J Bonar White of Atlanta then national first vice president the Woman's Auxiliary to the American Medical Association accepted it. It was on March 30, 1842 that Dr Crawford W Long, a Georgia physician administered the first ether anesthetic at his office in Jefferson. Mrs Y Harris Yarbrough of Milledgeville, is state chairman of Doctor's Day. The observance calls for some act of kindness, gift or tribute to the medical profession.

### Iowa

On January 19 members of the Woman's Auxiliary to the Pottawattamie County Medical Society entertained at a dinner to honor physicians who had practiced in the county for forty years or more. The dinner was held in Council Bluffs. Mrs William R Hornaday of Des Moines state president addressed the auxiliary on February 16 in Council Bluffs. The Objec-

tives of the Auxiliary." Officers for 1942 are Mrs Grant Augustinc, president, Mrs Robert S Moth, vice president, Mrs John P Cogley, secretary, and Mrs Sydnor D Maiden, treasurer.

### New Jersey

Through the generosity of Dr and Mrs Wells P Eagleton of Newark there was recently added to the Academy of Medicine of Northern New Jersey a new building. This means that in addition to holding its meetings at the academy, the Essex County auxiliary may now do so in its own rooms. A meeting room and lounge are for the use of the auxiliary members. A streamline kitchen holds the promise of many nice parties. The Red Cross Roll Call for Essex County has just been completed, and the auxiliary's booth was responsible for getting 498 new memberships. Members worked on the Community Chest drive and also on the sale of stamps for the Prevention of Tuberculosis League. Many members are active on the local Defense Council. Mrs Frank Bien, program chairman of the Essex County auxiliary, has a plan for those programs which are nonmedical, one of the program committee will read a five minute paper written by a local physician on a medical subject. This was tried out with success at the last meeting.

### New York

Columbia County auxiliary at the business meeting in Hudson, January 27, donated \$10 to the Red Cross war fund drive.

At the last meeting of the Fulton County auxiliary Mrs Alfred Madden, state legislative chairman, spoke on "What Physicians Wives Can Do in the State Program of Medicine." After the meeting the members did Red Cross work.

The outstanding project of the Oneida County auxiliary for the year is "blood typing." Within the group there are two first-aid units.

The Nassau County auxiliary sponsored a nutrition forum in February.

A general plan of defense work is being carried on by Onondaga County. At the last meeting, Mrs James R Wilson gave an outline on "Organized Housewives." The March meeting will be an heirloom party. In April Dr Louis H Bauer will speak on "Nutrition."

### Wisconsin

Mrs W T Clark and Mrs T J Snodgrass gave reports of the state meeting held recently in Madison. The meeting was conducted by the president, Mrs H E Kasten Beloit.

The Woman's Auxiliary to the Brown-Kewaunee-Door County Medical Society met at the home of Mrs L D Quigley, Green Bay, recently. Twenty-five members were present. Dr Mary Allen of the Bureau of Maternal and Child Health of the state board of health spoke on her work in child health centers.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

### ALABAMA

**Dr Austin Appointed State Health Officer**—Dr. Burton F. Austin, Montgomery, has been chosen state health officer to succeed the late Dr. James N. Baker, Montgomery. Dr. Austin, who had been acting health officer, is a native of Marl and graduated at the University of Alabama School of Medicine, University, in 1917. He served in the U. S. Army in France in the first World War and in 1920 joined the state department of health as health officer of Morgan County and later served as health officer of Madison County and district health officer in charge of thirty north Alabama counties. In 1935 he was named director of the state bureau of hygiene and nursing, now the bureau of maternal and child health, a position he held at the time of Dr. Baker's death last November.

### CALIFORNIA

**Portrait of First President of State Society**—The California Medical Association has been given a portrait of Dr. Benjamin Franklin Keene, one of its founders and first president. The picture is the gift of Mrs. J. E. Hays, Atlanta, Ga., granddaughter of Dr. Keene, who is state historian and director of the state department of archives and history. Dr. Keene, originally of Georgia, was one of seventy-six members of the profession from sixteen counties of central and northern California who met at Sacramento on March 12, 1856 to form a state society. Dr. Keene, state senator from El Dorado County, was elected president. He died the following September.

**Will Provides for Tuberculosis Foundation**—The establishment of a foundation for the prevention and treatment of tuberculosis has been provided for in the will of Charles H. Hastings in memory of his father, Charles Cook Hastings. The will stipulates that the Charles Cook Hastings Home be built either on "several large parcels of property near Beaumont, Calif., Banning, Calif., or on the Mesa Alta Ranch, near Pasadena, which is also Hastings property. The will instructs the executors to build a sanatorium to be conducted and maintained on a charitable basis. The Hastings estate is reported to amount to more than two million dollars. After payment of annuities to friends and servants, the entire estate will go to the foundation.

### CONNECTICUT

**Sesquicentennial Celebration of State Society**—The Connecticut State Medical Society will observe its one hundred and fiftieth anniversary at Wesleyan University, Middletown, June 3-4. Included among the speakers not mentioned in THE JOURNAL, February 21, page 655, are

Dr. Albert H. Miller, Providence, R. I., New England, The Cradle of Surgical Anesthesia  
Dr. Henry S. Ruth, Merion Station, Pa. Trends in Spinal Anesthesia  
Dr. George M. Lewis, New York Recent Advances in Practical Mycology  
Dr. Walter Guernsey Frey Jr., New York, Elisha North, Pioneer Connecticut Ophthalmologist  
Dr. Warren B. Davis, Philadelphia, Deformities of the Face and Their Correction  
Dr. Harry D. Sonnenschein, New York Office Procedures for Foot and Ankle Diseases  
Dr. Charles Bradley, East Providence, R. I. Diagnostic and Therapeutic Aspects of the Problem of Behavior Disorders in Children  
Mr. John J. Bloomfield, National Institute of Health, Bethesda, Md., War's Influence on Industrial Medicine  
Dr. James H. Biram, Hartford Treatment of Industrial Burns with Sulfathiazole  
Dr. John C. Whitehorn, Baltimore, Psychiatry as a Basic Medical Science  
Dr. Paul P. Swett, Bloomfield History of Orthopedic Surgery in Connecticut  
Dr. Harry E. Stewart, New Haven Physical Therapy in War Injuries  
Dr. Edwin Parker Hayden, Boston, Anerobic Perianal and Perirectal Infections  
Dr. Lewis G. Cole, New York Reminiscences of the Early Days of Roentgenologic Diagnosis

One session will be devoted to "Medicine of the Present and the Future." On the second day there will be a "historical meeting." Dr. Logan Clendening, professor of clinical medicine and history of medicine, University of Kansas School of Medicine, Kansas City, Kan., will deliver the oration of the day on "Opposition to Change as a Contribution to Social Progress." The anniversary dinner will be addressed by Col. Fred W. Rankin, President-Elect, American Medical Association.

### ILLINOIS

**Society News**—At the annual meeting of the Mercer County Medical Association, April 14, at Aledo, Dr. Norbert C. Baiwasser, Moline, spoke on "Diagnosis and Treatment of Cutaneous Maligancies."—Dr. Donald K. Hibbs, Chicago discussed "Urology in General Practice" before the Adams County Medical Society on March 10.

**New Tuberculosis Officers**—Dr. Frederick M. F. Mervner, Peoria, was reelected president of the Illinois Tuberculosis Association at its annual meeting in Danville, April 18. Other officers include Drs. William J. Bryan, Rockford, and Arthur S. Webb, Glen Ellyn, vice presidents, and John P. Denby, Carlinville, treasurer. Mary B. Meade, D.D.S., Carlinville, is secretary.

**Subsidized Tumor Diagnostic Service**—The state department of health has opened another state subsidized tumor diagnostic service at the Burnham City Hospital in Champaign. This is the fourth project of its kind to be established by the state department of health in cooperation with local county medical societies. Similar projects are now under construction at DuQuoin and Ottawa.

### Chicago

**Alumni Banquet**—The medical division of Northwestern University Alumni Association will hold its seventy-fifth annual faculty-alumni reunion dinner in the grand ballroom of the Knickerbocker Hotel, May 29, at 6:30 p.m.

**Refugee Wins Right to Take Examination to Practice**—A writ of mandamus to force the state department of registration to permit Dr. Martha Rosin, a refugee physician from Germany, to take an examination for a license to practice medicine was issued on May 13 by Circuit Judge John Prystalski, according to the Chicago Tribune. Dr. Rosin is 38 years old and came here in 1940. In February 1941 the Illinois board ruled that no application for examination to practice medicine would be accepted from graduates of foreign schools. Dr. Rosin claims to have graduated at the University of Freiburg in 1930. She is reported to have applied for citizenship.

**Amante Rongetti Leaves Prison**—Amante Rongetti was released from the Joliet Penitentiary on May 9 after serving the maximum period under his sentence with full time off for good behavior, newspapers report. In 1930 Rongetti was sentenced to prison for from one to fourteen years for manslaughter on a charge of causing a death through an illegal operation. He began his sentence on Oct. 17, 1931, having been found guilty of violation of the Harrison Narcotic Act. The U. S. Supreme Court denied the plea of Rongetti for a review of the Illinois Supreme Court decision affirming his conviction on a charge of manslaughter. In Rongetti's first trial he was sentenced to death. When the supreme court granted a new trial he was found guilty of manslaughter. This verdict was set aside at the third trial followed. His license to practice medicine was revoked by the state department of registration and education May 4, 1932, on the ground of his conviction of manslaughter.

### MASSACHUSETTS

**Institute for Hospital Administrators**—The Second New England Institute for Hospital Administrators will be held at Harvard Medical School, Boston, June 15-25, under the chairmanship of Dr. Charles F. Wilinsky, executive director and superintendent, Beth Israel Hospital, Boston. This year the emphasis will be placed on the role of hospitals in the war. The institute will be conducted by the American College of Hospital Administrators, the New England Hospital Association in cooperation with hospital associations of the New England states, New York, New Jersey and Pennsylvania, with Harvard Medical School, Boston University School of Medicine and Tufts College Medical School, all in Boston.

**Dr. Walter Cannon to Retire**—Dr. Walter B. Cannon, George Higginson professor of physiology at Harvard Medical School, Boston, will retire with the title emeritus on September 1. Dr. Cannon was born in Prairie du Chien, Wis., in 1871 and graduated at Harvard Medical School in 1894. He was instructor in zoology there from 1899 to 1900 in physiology from 1900 to 1902 and assistant professor from 1902 to 1906. He has held his present professorship since 1906. Many honors have been accorded to Dr. Cannon during his teaching career, including honorary degrees, prizes and memberships in special societies. He received the Distinguished Service Medal during the World War. In 1939 he was elected president of the American Association for the Advancement of Science.

## MISSISSIPPI

**Courses on Nutrition**—The state extension service and the department of home economics of the Mississippi State College, State College through the state nutrition committee, are sponsoring a series of three one day nutrition meetings for three successive months in all the counties of the state

**Changes in Health Officers**—Dr John W Dabbs, formerly health officer of Geneva County, Ala, has been named health officer of the Oktibbeha County Health Department at Starkville —Dr Revis A Brannon Jr, Utica, has been named director of the southeastern health district covering George, Green, Stone and Perry counties —Dr George E Riley, Jackson, has been named health officer of Clay County, with offices in West Point —Dr Victor P Genge is the new director of the Lafayette County health department succeeding Dr Thomas L Owings, Oxford, who resigned to enter private practice in Alabama —Dr Joe H Price, formerly district health officer, McLeansboro, Ill, has been appointed health officer of Tishomingo County, succeeding Dr William R Armstrong, Iuka who has entered army service

## NEW JERSEY

**Society News**—The Society of Surgeons of New Jersey will hold its spring meeting May 27 at Montclair clinics will constitute the day's program An evening dinner will be addressed by Circuit Judge Joseph G Wolber, Montclair —The Cumberland County Medical Society was addressed on April 14 at Millville by Dr George Wilson, Philadelphia on 'Shock Treatment in Mental Disease' —Dr George F Hoch New York, discussed Treatment of Urinary Tract Infection before the Passaic County Medical Society on May 14 in Paterson

## NEW YORK

**State Society Endorses Insurance Plans**—The house of delegates of the Medical Society of the State of New York has approved and voted to 'sponsor and support in every manner possible three corporations in the state offering medical insurance to subscribers according to the New York Times The groups that were given endorsement are the Western New York Medical Plan, Inc, of Buffalo Medical and Surgical Care Inc Utica, and Medical Expense Fund of New York Inc of Brooklyn, which are said to have conformed to the principles prescribed by organized medicine for the protection of the interest of both the public and the profession in the organization and operation of medical insurance' The resolution acknowledging the society's action was adopted without a dissenting vote

**Cancer Teaching Day**—June 18 has been designated 'cancer teaching day' in Buffalo with sessions at the Hotel Statler The sponsoring agencies are the Medical Society of the County of Erie, University of Buffalo School of Medicine Eighth District Branch of the New York State Medical Society New York State Medical Society and the division of cancer control of the state department of health The speakers will be

Dr Chevalier L Jackson Philadelphia Cancer of the Larynx—Early Diagnosis and Criteria for the Selection of Methods of Treatment  
Dr George F Cabill New York Hematuria and Cancer of the Genito urinary Tract

Dr Frank E Adair New York Carcinoma of the Breast—Diagnosis Treatment and Results

Dr Thomas E Jones Cleveland Surgery and Radiation in the Treatment of Malignancies of the Colon and Rectum

Dr Cornelius P Rhoads, New York will address the dinner session on Recent Studies in the Production of Cancer by Chemical Compounds, the Conditioned Deficiency as a Mechanism

## New York City

**Technician Killed While Demonstrating X-Ray Machine**—Miss Edith Fox, x-ray technician and assistant to Dr Arthur S Unger director of the division of roentgenology at Sydenham Hospital suffered a fatal electric shock on May 6 shortly after she had started to demonstrate an x-ray machine to a class of three technician students at the hospital, according to the New York Times Miss Fox is said just to have turned the machine on and was stepping up the voltage when the accident occurred The machine was of the so-called shock proof type

**Personal**—Dr William M Dunning a charter member of the Bronx County Medical Society was given a dinner on April 25 by the Bronx Eye and Ear Infirmary in recognition of his completion of fifty years in the practice of medicine —Dr

Maximilian A Ramirez, president of the Medical Society of the County of New York was guest of honor at a dinner on April 23 Among the speakers were Drs Edward M Bernecker, commissioner of hospitals, Samuel J Kopetzky George Baehr, John S Kenney and Nathan O Ratnoff Dr Adolph G G DeSanctis was toastmaster

**Academy Commends Psychiatric Clinics**—The public health relations committee of the New York Academy of Medicine commending both the diagnostic and the treatment clinic for psychiatric cases of the children's division of the domestic relations court as important and necessary, recommended in a report made public on April 28 that the treatment clinic be financed out of city funds and that it have a larger staff, including at least two full time psychiatrists, one or more psychiatric social workers and "pediatricians who would be responsible for general medical work"

**Course on Tropical Medicine**—The New York Post-Graduate Medical School, Columbia University, will offer a five day course on tropical medicine May 25-29, under the direction of Dr Zacharias Bercovitz Included among the lecturers will be

Dr Eugene R Kellersberger executive director American Mission to Lepers African Trypanosomiasis

Dr Walter J K Clothier of the Presbyterian Board of Foreign Missions Filariasis

Dr Thomas T Mackie Amebiasis Diagnosis Differential Diagnosis Treatment and Prophylaxis

Dr Henry E Meleney Relapsing Fevers

Dr Ward J MacNeal Yellow Fever Diagnosis and Preventive Vaccination

Dr Howard Fox Syphilis and Pinta

Dr Bercovitz Tropical Hygiene

Dr Stuart P Seaton Princeton N J for seventeen years a medical missionary in Hainan South China

## PENNSYLVANIA

**Institute on the Exceptional Child**—'The Wartime Adjustment of the Exceptional Child' will be the theme of the eighth institute on the exceptional child under the auspices of the child research clinic of the Woods Schools, Langhorne, May 26 The speakers will include

Dr Erich Benjamin Baltimore Social Adjustment During Early Childhood and Its Failures

Caroline B Zachry Ph D New York Educational Philosophy for the School for Exceptional Children

Emily T Burr Ph D New York Vocational Training for the Exceptional Child During the War Emergency

Dr Paul V Lemkau first lieutenant M C U S Army Washington D C Military Service

James H S Bossard Ph D Lansdowne The Impact of War on the Family

**Combined Annual Sessions**—The annual clinic of the Westmoreland County Medical Society and the annual meeting of the Tenth Councilor District Medical Society were held in Greensburg on May 7 The speakers included

Dr William A McHugh Jr Umontown Congenital Hypertrophic Pyloric Stenosis

Dr Thomas G McLellan Connellsville Glaucoma in General Practice

Dr Samuel A Ruben Washington Does Cesarean Section for Prematures Offer Better Chances for Viability Than Vaginal Delivery

Dr Elmer Higberger Jr Greensburg Pneumothorax

Dr David P McCune McKeesport Hematuria

Dr La Mar H Davenport Du Bos Ruptured Peptic Ulcer

Dr John W Fredette Pittsburgh Sulfonamides in Bone and Joint Surgery

At this session fifty year testimonial certificates were presented from the state medical society to the fellow members of the Tenth Councilor District who have been in practice more than fifty years

## Philadelphia

**Premature Baby Deaths**—On July 1 the Philadelphia department of health will launch a campaign to reduce the death rate of babies born prematurely Simultaneously a city ordinance will go into effect compelling physicians to report premature births to the department of health within two hours The report stated that the mortality rate for premature babies in the city is 135 per thousand

**Medal for Scholastic Standing**—The will of the late Dr Howard A Sutton stipulates that his medical instruments and books are to be offered for sale to members of the medical fraternity Alpha Mu Pi Omega the proceeds to be used to purchase medals to be awarded annually to the undergraduate member of the fraternity who shall have attained the highest scholastic standing during the preceding year at the University of Pennsylvania Dr Sutton at one time served on the faculty of the department of anatomy at the university medical school He died March 21

## WEST VIRGINIA

**Personal**—Dr William E McIlvain, Charleston, director of the bureau of tuberculosis of the state health department and for the past two years in charge of the state's mobile x-ray unit, resigned, April 6, it is reported, to enter the U S Navy

**State Health Conference**—The West Virginia State Health Conference was held at Martinsburg, May 11-13, with Dr Victor H Vogel, assistant chief, division of mental hygiene, U S Public Health Service, Washington, D C, giving the opening address, on "Mental Health in War and Peace" Other features included a symposium on communicable disease control and a panel discussion, led by Dr Reginald M Atwater, New York, on "Planning a Local Health Program in the Light of the Present Crisis"

**Joe Savage in the Air Corps**—Mr Joe Savage, for many years executive secretary of the West Virginia Medical Association and business manager of its journal, has been granted a leave of absence for the duration of his service in the Army Air Corps Captain Savage is stationed at Miami Beach Mr Charles Lively has been appointed acting executive secretary He has been serving as clerk of the U S District Court for the Southern District of West Virginia Between 1933 and 1941 he was clerk of the West Virginia Senate

## GENERAL

**Dermatologists Cancel Meeting**—The American Dermatological Association announces that its 1942 meeting has been postponed The meeting was to be held in Hot Springs, Va, May 31-June 4

**Class Reunions and Dinners**—There will be a reunion of the class of 1932 of the University of Pennsylvania School of Medicine at the Hotel Madison, Atlantic City, June 10, 6 to 8 p m Admission \$3

**Plastic Surgeons' Meeting**—The American Association of Oral and Plastic Surgeons will hold its annual meeting at the Barbizon-Plaza Hotel, New York, May 28-30, under the presidency of Dr Jerome P Webster, New York Clinics will be held at St Clare's, Presbyterian, Lenox Hill, Post-Graduate and Polyclinic hospitals The association has always held a clinical session, but this year a number of short papers will be presented on subjects of current interest

**American Otological Meeting**—The seventy-fifth meeting of the American Otological Society, Inc, will be held at the Marlborough-Blenheim Hotel, Atlantic City, N J, May 28-29, under the presidency of Dr Ernest M Seydell, Wichita, Kan Among the speakers will be

Dr Ralph A Fenton, Portland, Oregon, The Influence of Aviation on Otology  
Dr John M Brown, Los Angeles Actinomycosis of the Temporal Bone  
Dr Hermon Marshall Taylor, Jacksonville, Fla Neurological Complications of Serum Sickness with Special Reference to the Ear  
Dr Hans Brunner, Chicago, Encephalography  
Drs Robert S Schwab and Richard R Carter, Boston, Electroencephalography in Relation to Otology

**American Orthopaedic Association**—The annual meeting of the American Orthopaedic Association will be held in Baltimore, June 3-6, under the presidency of Dr George E Bennett, Baltimore The tentative program includes the following speakers

Dr Kellogg Speed, Chicago, Postmetastatic Survival of Osteogenic Sarcoma  
Dr Henry W Meyerding, Rochester, Minn, Spondylolisthesis  
Dr Wallace H Cole, St Paul, Pin Fixation of War Fractures  
Dr Lee C Farr, Wilmington, Del, Indications for the Intravenous Use of Amino Acid Mixtures in Surgery  
Dr William E Gallie, Toronto, Ontario, Canada, Fracture of the Odontoid Process  
Dr Carl E Badgley, Ann Arbor, Mich, Spontaneous Fracture of the Femur Following Radiation Therapy for Pelvic Malignancy  
Dr Luther Vargas, Brazil, S A, Repair of Complete Acromioclavicular Dislocation with the Aponeurosis of the Short Head of This Biceps

**American Ophthalmological Society**—The seventy-eighth annual meeting of the American Ophthalmological Society will be held at The Homestead, Hot Springs, Va, June 1-3, under the presidency of Dr Allen Greenwood, Boston Among the speakers will be

Dr William H Crisp, Denver, A New Cross Cylinder Test of Astigmatic Axis, Without Use of Test Type  
Drs Peter C Kronfeld, Helen Isabelle McGarry and Homer E Smith, Chicago, Effect of Mydriatics on the Intraocular Pressure in "Primary" Wide Angle Glaucoma  
Drs Cecil S O'Brien and James H Allen, Iowa City, Allergic Keratoconjunctivitis  
Drs Phillips Thygeson and Alton E Bracey, New York, Local Sulfonamide Therapy of Catarrhal Conjunctivitis  
Drs Henry P Wagener and J Grafton Love, Rochester, Minn, Studies of the Fields of Vision in Cases of Rathke Pouch Tumors  
Dr Algernon B Reese, New York, Precancerous Melanosis and Malignant Melanoma of the Conjunctiva

**American Human Serum Association**—The annual meeting of the American Human Serum Association will be held at the Chalfonte-Haddon Hall, Atlantic City, N J, June 8, under the presidency of Dr Maurice A F Hardgrove, Milwaukee Among the speakers will be

Earl W Flosdorf, Ph D, Lansdowne, Pa, Drs Harriet M Felton, Philadelphia, and Anthony Bondi, Rochester, N Y, Incidence of Agglutinins Specific for H Pertussis and B Parapertussis in Sera from Adults and Children  
Edwin J Cohn, Ph D, Cambridge, Mass, Properties of the Various Globulins and Albumins of Serum and Plasma  
Drs Frank W Hartman and Henry N Harkins, Detroit, The Physical Properties and Physiological Responses to the Intravenous Injection of Pectin Solutions  
Dr Wilhelm C Hueper, New York, Hematic and Organic Reactions Caused by Several Macromolecular Plasma Substitutes  
Drs Ernest C Muirhead and Joseph M Hill, Dallas, Texas, The Rationale of Concentrated Plasma Protein Solution in the Treatment of Shock

**Association of Genito-Urinary Surgeons**—The fifth annual session of the American Association of Genito-Urinary Surgeons will be held at the Hotel Hershey, Hershey, Pa, May 27-29, under the presidency of Dr Homer G Hamer, Indianapolis Included among the speakers will be

Dr Thomas P Shupe, Cleveland, Division of Aberrant Blood Vessels to the Kidney Without the Production of an Infarct—Report of a Case  
Drs William F Brasch, and William W Wood Jr, Rochester, Minn, Clinical Perinephritis and Blood Pressure  
Dr Emerson C Smith, Montreal, Quebec, Canada, The Upper Urinary Tract in Cases of Neurogenic Bladder  
Drs John K Ormond, George H Wadsworth and Harold V Morley, Detroit, Pancreatic Lesions Confusing Urologic Diagnosis—Report of Two Cases  
Drs George Gilbert Smith and Wyland F Leadbetter, Brookline, Mass, Effect of Irradiation on the Lower Ureters  
Dr Alexander Randall, Philadelphia, Eight Year Results of Castration for Prostatic Malignancy  
Drs Charles M McKenna and Joseph H Kiefer, Chicago, Pseudohermaphroditism Due to Hyperactivity of the Adrenal Cortex

**Association for the Surgery of Trauma**—The fourth annual session of the American Association for the Surgery of Trauma will be held at the Copley-Plaza Hotel, Boston, June 4-6, under the presidency of Dr Henry C Marble, Boston Included among the speakers will be

Dr Arthur W Allen, Boston, Peripheral Circulation in Relation to Trauma  
Dr Idys Mims Gage, New Orleans, Traumatic Arterial Aneurysms of the Peripheral Arteries The Pathology, Clinical Manifestations, Diagnosis and Treatment  
Dr Garrett M Brownrigg, St John's, Newfoundland, Frosthite and Allied Conditions as Observed in Shipwrecked Mariners  
Drs George M Curtis and Louis C Roettig, Columbus, Ohio, Traumatic Rupture of the Spleen  
Dr Sidney C Wiggan, Boston, Anesthesia for the Surgery of Trauma  
Dr John A Caldwell, Cincinnati, Subtrochanteric Fracture of the Femur—An Advantageous Approach for Open Fixation

The annual banquet Friday evening will be addressed by Comdr Albert Warren Stearns, U S N R Medical Corps on "The Medical History of the Siege of Boston" and Col Joseph A MacFarlane, Toronto, Ont, Canada, consulting surgeon with the Canadian Forces in Britain

**Neurological Meeting**—The sixty-eighth annual meeting of the American Neurological Association will be held at the Drake Hotel, Chicago, June 4-6, under the presidency of Dr Lewis J Pollock, Chicago Included among the speakers will be

Drs Loyal Davis and George E Perret, Chicago, Cerebral Thrombosis Obliterans  
Dr Walter L Bruetsch, Indianapolis, Rheumatic Endarteritis of Cerebral Vessels Sequel of Rheumatic Fever  
Drs Franklin G Ebaugh, Clarke H Barnard and Karl T Neuberg, Denver, Fatalities Following Electric Convulsive Therapy  
Drs Ralph W Gerard, Julian M Tolins and David B Clarke, Chicago, Spinal Ganglion Respiration  
Dr Charles Davison, New York, Effect of Vitamin E Therapy on the Central Nervous System in Amyotrophic Lateral Sclerosis  
Drs Henry A Riley and Maurice Frocht, New York, Myasthenia Gravis Incidence in Two Sisters  
Dr Victor E Gonda, Chicago, A New Tendon Stretch Reflex and Its Significance in Lesions of the Pyramidal Tracts

The Chicago Neurological Society will give a luncheon at the Drake Hotel Friday afternoon for the members of the association The annual dinner will be held Friday evening at 7:30 The American Association of Neuropathologists will hold its meeting at the Drake Hotel, June 4

**Committee on the Common Cold**—The American Association of Industrial Physicians and Surgeons announces the formation of a new committee on the common cold Dr A G Kammer, medical director, Inland Steel Company, Watling Street, East Chicago, Ind, is chairman of the committee, members include Drs Mark W Garry, Montreal, mining Company, Montreal, Wis, Charles E Shannon, director, Marshall Field Store, Chicago, James C Clark, Sand Springs, Okla, Howard G Lafferty, Sharon, Pa, Michael J Lepore, chief, nutrition clinic, Columbia U

Medical Center, New York. The committee will study the preventive aspects of the common cold and submit reports to the president of the association of industrial physicians and surgeons. Physicians who are investigating one method or the other of cold prophylaxis and who do not intend to publish reports of their studies are invited to submit their data for study and correlation.

**Meeting of Pathologists**—The American Society of Clinical Pathologists will hold its twenty-first annual meeting and ninth seminar at the Benjamin Franklin Philadelphia, June 4-7, under the presidency of Dr. John L. Lattimore, Topeka, Kan. whose address will be entitled "The Pathologist as a Physician. Among the speakers will be

Dr. Virgil H. Moon, Philadelphia. The Dynamics of Shock as Related to Diagnosis and Treatment.  
Dr. Israel Davidson and Beatrice Toback, M.S., Chicago. The Rh Factor: An Antigenic Analysis.  
Dr. Philip Levine, Newark, N. J. The Role of Isoimmunization in Erythroblastosis and Other Conditions.  
Dr. Fritz Levy, Elkins, W. Va. Megakaryocytes and Blood Platelets.  
Dr. Albert B. Sabin, Cincinnati. The Natural History of Human Poliomyelitis.  
Dr. Herbert Lund, Cleveland. Scientific Evidence Useful in Establishing the Time of Death.  
Dr. Samuel A. Levinson and Harold C. Voris, Chicago. Cerebral Injuries by Mechanical Violence.

A symposium on medicolegal autopsy will be held Saturday morning. The annual banquet Saturday evening will be addressed by Col. James E. Ash, M.C., U.S. Army, Washington, D.C., Capt. Charles W. O. Bunker, medical director, U.S. Navy, Bethesda, Md. and Dr. Morris Fishbein, Editor, THE JOURNAL, Chicago.

**American Gastro-Enterological Meeting**—The forty-fifth annual meeting of the American Gastro-Enterological Association will be held at the Hotel Claridge Atlantic City, June 8-9, under the presidency of Dr. Russell S. Boles, Philadelphia. The scientific program will open with a symposium on the diseases of the digestive tract in relation to the present emergency. Drs. Zacharias Bercovitz, New York, Clifford J. Barborka, Chicago, Donald T. Chamberlin, Boston, Lemuel C. McGee, Wilmington, Del., and Lee C. Gatewood, Chicago. Other speakers on the program will include

Dr. Donald Sheehan, New York. Relationship of the Hypothalamus to the Large Bowel.  
Drs. George B. Eusterman and Byrl R. Kirklin, Rochester, Minn. Significance of the Malfunctioning and Closed Stoma in the Gastro-enterostomized Stomach.  
Dr. Donovan C. Browne, New Orleans. Gastric Changes in Advanced Pulmonary Tuberculosis.  
Drs. Rudolf Schindler and Marie Ortmyer, Chicago. Histopathology of Chronic Gastritis.  
Drs. Jack Edward Berk, Jacob Earl Thomas and Martin E. Rehfuss, Philadelphia. The Duodenal Acidity and Neutralizing Ability as Criteria of the Acid Factor in Duodenal Ulcer.  
Drs. Grant H. Laing, James M. Beazell and Andrew C. Ivy, Chicago. The Relationship Between Roentgenographic Abnormalities of the Gallbladder and Constipation.

At the annual dinner Dr. Max Einhorn, New York, will be presented with the Friedenwald Medal by Dr. William Gerry Morgan, Washington, D.C. Dr. Frank H. Lahey, Boston, President of the American Medical Association will be the principal speaker, on "Medicine and the War."

## LATIN AMERICA

**Personal**—Dr. Carlos Bonorino Udaondo, Buenos Aires, Argentina was recently appointed honorary professor of the Faculty of Medical Sciences of the University of Buenos Aires. Dr. Udaondo was dean of the faculty from 1929 to 1931.

**Neuropsychiatric Reunion**—The third reunion of Pan American neuropsychiatric societies will be held in Buenos Aires in November. Members of the board of directors of the committee of organization of Argentina include Drs. Nerio Rojas, professor of legal medicine, Faculty of Medicine of Buenos Aires, president Arturo Ameghino and Vicente Dimitri vice presidents and Felipe M. Cia secretary. All correspondence should be addressed to Dr. Rojas, Catedra de Medicina Legal de la Facultad de Ciencias Medicas de la Universidad de Buenos Aires.

## FOREIGN

**Public Health Under Hitler's Rule**—According to Dr. Conti, reich health leader, in the *Völkische Beobachter* as quoted by NDZ, March 27, the typhus menace has been banished. Typhus in March decreased 70 per cent as compared with the number of new cases in December 1941. An epidemic of typhus is said not to have developed in the reich territory during the winter but in 1941 there were 165 cases among German nationals and 121 among Jews in the old reich. In the incorporated eastern territories there were 34 cases among the

Germans and 2,750 among the Jews. In Berlin itself there were only 4 cases in February. Anticipating the danger, Dr. Conti said all necessary precautions were taken in time, the German frontier having been protected by a network of delousing stations. In 1939 and 1940 precautionary measures were started with the repatriation of Germans from districts near Russia. Three thousand people from Volhynia and Galicia were deloused every day in Lodz alone. There has been a shortage of soap rendering delousing difficult, but the Germans have developed soapless preparations, it is said, which are equally effective. For Germans in Greater Germany the danger of typhus is now said to be practically nonexistent.

According to Havas, March 22, the depopulation of France has increased since 1935, and the death rate exceeds the birth rate. The secretary of state for national education M. Caropine, has therefore organized courses and lessons on demography in schools, so that children may learn about this danger to their country.

Stefani, March 24, states that the National Congress of War Surgery will be held at Rome late in May. Presiding will be General Alfredo Ingravalle, director general of the army medical department, and Prof. Raffaele Bastanelli, secretary of the National Fascist Syndicate of Doctors. Delegates from Germany and other axis countries are expected to attend.

The momentous negligence of France confronts both party and state today with great tasks in their fight against tuberculosis. According to NDZ, March 18, tuberculosis in Alsace has reached an incidence twice as high as in Baden. Dr. Steininger, who was called to Strasbourg as tuberculosis consultant, Dr. Sprauer, head of the state health services, and Dr. Pichlau, gauamtsleiter for people's health in the NSDAP, gave an interview in which they are reported to have said that tuberculosis has spread because, under French rule, restrictions against this disease were directed chiefly to safeguard the livelihood of the patients. But the payment of grants is no solution to the problem, the community must help these patients by timely diagnosis and treatment and not merely by sympathizing with them. Tuberculosis centers have been set up in the thirteen health offices in Alsace, equipped with x-ray apparatus and staffed by experts. The Strasbourg tuberculosis center has given expert advice to 1,200 patients a month. The x-ray mass examination unit of the office for the people's health which was set up explicitly for Alsace, has since January 1941 taken about forty thousand roentgenograms of chests and in this way has found many cases of tuberculosis which previously were unknown. All these patients, regardless of their financial status will be treated, it is said without delay. The insurance institute will pay in full for the insured patients, and the welfare institutions will pay for those who are unable to pay themselves. In the case of farmers and independent craftsmen who are not insured and who have insufficient means, the tuberculosis relief scheme of the National Socialist Welfare Organization will pay the expense.

Since several sanatoriums owned by the city of Paris are now in danger zones, the authorities have acquired the De Launay Estate at Reuilly and converted it into a one hundred and fifty bed sanatorium for patients with tuberculosis, according to Radio Lyons, March 25.

## CORRECTION

**New York Psychoanalytic Society and Institute**—The New York Psychoanalytic Society and Institute issued a statement on Nov. 25, 1941 in which, among other things, it claimed to be the only organization for training in psychoanalysis chartered by the University of the State of New York. The New York Psychoanalytic Society and Institute now desires to correct the error by pointing out that the New York Psychoanalytic Institute was chartered by the state of New York and not by the University of the State of New York. The Commissioner of Education of the State of New York gave consent to the filing of a charter but such consent was not subject to construction as an approval of the Education Department, the Board of Regents or the Commissioner of Education of the purposes and objects of the institute. It is further pointed out in the statement of correction issued by the New York Psychoanalytic Society and Institute that as far as the University of the State of New York is concerned the status of the New York Psychoanalytic Institute does not differ from that of the American Institute for Psychoanalysis. This will also correct the last paragraph of the general news item in THE JOURNAL, April 25, page 1507, entitled "Statement by New York Psychoanalytic Society and Institute."

#### The Status of Medical Women in the Fighting Services

In 1939 medical women were recruited for the fighting forces. They were offered "relative rank" without commissions but with similar status and allowances as men. This offer was accepted, but when the government gave commissions to officers of the women's services, including the nursing service, trouble began. Medical women were offered commissions in these services. They complained that, instead of having commissions in the medical services on equal terms with men, they were asked to work with the army medical corps, though not an integral part of it. Although financially they were equal to men, their status was inferior. As a result of negotiations they were allowed to retain their old status of "relative rank" if they preferred, but this does not satisfy them. The Medical Women's Federation, which exists to uphold the rights of medical women, holds that the commissions offered in the women's forces do not secure professional equality between men and women doctors. This is a fundamental principle of the federation. It says that medical women volunteered for service in, not with, the medical services.

#### The Physiologic Limit to Sprinting for War Production

The Industrial Health Research Board of the Medical Research Council has issued a report on work in war production based on investigations of fifty factories employing two hundred thousand workers. The time lost through sickness, injury and absence without permission varied with the weekly hours of work. It was usually low when the hours were less than sixty weekly but increased as the hours increased up to seventy-five. The findings suggest that over an extended period the hours should not generally exceed sixty or sixty-five for men and fifty-five to sixty for women. The workers were stimulated to increased output after the fall of France. Although it was physiologically impossible to maintain the maximum level reached, output has since remained above the previous level. The beneficial effect of a reduction of excessive hours with inauguration of staggered holidays was reflected in an increase in the rate of working afterward. Adjustment to factory life was difficult for women unaccustomed to it, particularly for those with domestic responsibilities.

The report concludes that man is not a machine, an idea which dies hard. For maximum production good health is necessary, and for this adequate food, regular periods of leisure and reasonable conditions of work. War time tends to obscure these truths. As man is not a machine, he has the power to "rise above himself" and by force of will to exceed his ordinary maximum. Hence the amazing success of emergency efforts. Unfortunately, industry often fails to acknowledge that the effort is extraordinary and complains when this becomes ordinary. The last war showed that after a number of hours the best will in the world cannot keep up the pace. Steady sustained effort pays better in the long run than violent spurts.

#### Precautions Necessary with Roentgen Rays

The damage sustained by surgeons when using the roentgen rays in the manipulation of fractures and the removal of foreign bodies has led the British X-Ray and Radium Protection Committee to draw up the following rules. The rays may be used in two ways. 1. Screening or taking roentgenograms, radiography should be the usual procedure and involve no exposure of the hands or person to a direct beam. 2. Manipulating the fracture under fluorescent screen control, this inevitably involves great risk and cannot be rendered safe, for the surgeon's hands

must come into the direct beam of the rays. Only in exceptional cases should this method be adopted, and then only on the responsibility and under the direction of the senior surgeon.

The operating room should be satisfactorily darkened. Lights should be dimmed as far as possible before screening, and no lights should face the surgeon. The previous films in the case should be seen and memorized and not scrutinized in a bright viewing box immediately before examination. It is essential that the surgeon should prepare his eyes for screening a minimum of five minutes in the dark should be allowed. This can also be attained by using a single red light in the room or by wearing dark or (preferably) red goggles for some minutes before screening. The apparatus should be operated by a radiographer specially trained. He should be given definite instructions by the radiologist as to the limits in which he must use the apparatus. The tube-screen distance should not be less than 20 or more than 30 inches. The apparatus should be set to give not more than 65 kilovolts. For thin parts and children a lower voltage is adequate, 3 milliamperes is the maximum screening current that should be used. As a safeguard an automatic "cutout" can be used. All apparatus should be shock proof. An aluminum filter of 1 or 1.5 mm should be fixed in the tube aperture, so as to furnish a total filtration of not more than 2 mm of aluminum. Cones or cylinders to limit the x-ray field are essential. The radiographer should watch to see that the beam is constantly kept within the limits of the screen. The hands of the operator or of the assistant should not come within the direct beam.

Manipulation of fractures under screen observation should be done only in exceptional cases, and the time occupied should be limited to a minute. Even with one rapid manipulation with the hands in the direct beam the tolerance dose may be much exceeded. The fluorescent screen fitted to the head and supplied with a hood is a very dangerous device which should never be used.

#### Feeding the Nation

The minister of food has given a review of his work in 1941 which shows that we have a nutritional policy of wide scope to keep the nation well in spite of war restrictions. The beginning of 1942 finds us fighting fit, and all the statistics indicate that we shall remain so during the year. "The Germans were determined to starve us," said Lord Woolton, minister of food "and the early part of 1941 was an anxious time for the ministry." Then the Americans came forward with generous supplies under the lend-lease act, and our seamen ensured their safe arrival. The result was that by the beginning of the third year of the war stocks were so improved that some of the bulk foods were higher than before the war. As the war has now become a world war, we must be continually prepared for variation in foods and in amounts. Provided there is enough of one thing or another, that is all which matters. Having collected the food there remains the equally complicated task of distributing it fairly. Lord Woolton claims that we are the only country at war which has been able to increase its ration.

With control of distribution goes control of prices. Taking certain food prices in 1914 (before the previous great war) as 100, the cost rose continuously to a peak of 278 in 1920. At the outbreak of this war we started with a figure of 138. This rose steadily to 170 in June 1940, since which time it has fallen to the present level of 164. The cost of food to the consumer has been stabilized both by price control and by subsidies, which now total \$500,000,000 a year. Bread has been the main subsidized food, but in 1941 eggs and potatoes were subsidized for the first time. Food has been directed to those who need it most—milk to children, adolescents, expectant and nursing mothers and invalids, extra rationed foods to industrial workers, more cheese and meals from war agricultural workers. Provision is about to be made for the job for 94 per cent of the miners.

## PARIS

(From Our Regular Correspondent)

March 19, 1942

## Tuberculosis and Food Restrictions

Since 1913 the mortality of tuberculosis has diminished 60 per cent in Paris and 44 per cent in all France. During the war of 1914-1918 there was a transitory increase in tuberculosis. Since the beginning of 1941 a continuous increase of tuberculosis has occurred, as pointed out at a meeting of the Academy of Medicine, Sept 2, 1941 by Prof Marcel Moine. In comparison to the first six months of 1939, the mortality due to tuberculosis of the respiratory organs increased in the first six months of 1941 by 20.4 per cent and of all other forms of tuberculosis by 30.4 per cent. The departmental laboratory of the Oise which does work for several dispensaries, reports that the frequency of requests for sputum examinations has increased 38 per cent at Beauvais and 101 per cent at Compiègne and that the positive bacteriologic examinations of new cases have increased. In comparison to 1938 there is the following increase of positive examinations per thousand samples examined in 1938, 54.3, in 1939, 59.1, in 1940, 72.2, in 1941, 211. Compared with 1938 the increase of bacillary intensity can be estimated to be 290 per cent.

At a meeting of the Société médicale des hôpitaux de Paris, Ravina stated that he observed a great number of first infections and many acute attacks in persons who until the last few months enjoyed perfect health. Ravina gives several reasons for this. The army took in a great number of formerly tuberculous persons. Weariness has resulted from overwork, alimentary insufficiency and captivity. The retreat of the armies, the exodus of the population, the poor conditions of life, have caused a revival of this disease. Moral factors as Laennec emphasized, have had a great part. Research is going on in order to classify the types of tuberculosis. It can already be stated that there are two main categories. 1. The form for which the outbreak goes back to June-September 1940 and which is caused by fatigue and moral shocks shows a tuberculosis type of a more polymorphic appearance and less grave prognosis. 2. The bacillary bronchopneumonia with rapid evolution, these cases have started since the beginning of 1941 and are chiefly due to food shortage.

At the same meeting Charles and François Flandin reported on an inquiry which they made at the hospital of St. Louis in Paris and in the private practice of various physicians into the influence of food restrictions on tuberculosis of the skin and lymph glands which until now have been without change. On the other hand, they have noted an increase in cases of Hodgkin's disease, of which the relationship to tuberculosis is believed to have been established by various research workers.

## Sulfonamide Therapy and Bronchiectasis

At a recent meeting of the Academy of Medicine, Professor Bezançon discussed the interesting problem of sulfonamide therapy in cases of bronchiectasis. Sulfapyridine reacts positively in acute typical pneumonia but often is ineffective in bronchopneumonia or abscess of the lungs. Bezançon supposed that the positive influence is chiefly in cases with fresh inflammation as soon as a lesion exists fragments of dead tissue hinder the bacteriostatic action of the drug. The same thing can be stated for war wounds. In order to make the action efficacious one has to clean the wound of dead tissue. Bezançon has observed however, that even in complicated pulmonary cases an unexpected positive result is sometimes obtained. In bronchiectasis the infection and the dilatation of the bronchi cause pain, cough and expectoration. The aim of sulfonamide treatment is not to cure the bronchial dilatation but to improve the state of the patient by fighting the infection. In 7 cases of

bronchiectasis treated with sulfapyridine the results have varied. A woman now 24 developed bronchiectasis at the age of 6 after bronchopneumonia. All search for tuberculosis was negative. The patient has incessant cough and cyanosis of the face and nails. She is very thin and has a temperature always over 38°C (100.4°F). The expectoration amounts to 300 to 400 cc a day. There was no result whatever obtained with any treatment. After the administration every day of 3 Gm of sulfapyridine for four days the temperature sank to 37°C (98.6°F), the expectoration diminished to 125 cc and the cyanosis diminished. During the twenty-five days of administration of the drug the patient's state was good then leukopenia developed and the treatment was stopped. For six days after this medication was stopped the improvement persisted. Then the expectoration increased to 400 cc, dyspnea and cyanosis reappeared and the temperature oscillated between 36.5 and 39.2°C (97.7 and 102.5°F). A blood examination showed 15,000 leukocytes. The medication was resumed and the patient's condition improved the next day. For a year 0.75 to 2.5 Gm of sulfapyridine a day has been given for ten days and then stopped for two or three days. The administration of sulfapyridine powder into the bronchi did not give positive results. The lesion itself has not been modified. The excellent results are always transitory, and as soon as the medication is suspended the symptoms reappear. Bezançon explains the various results among the other cases as due to the different forms of bronchiectasis. In many cases of bronchial dilatation, as in many tuberculous cavities, the expectoration does not come from morbid foci alone but also from the neighboring bronchi. Under these conditions the failures of sulfonamide treatment are comprehensible, as the disorders do not result from infection alone.

## Surgical Treatment of Cerebral Hemorrhage

Lhermitte and Guillaume, at a recent meeting of the Academy of Medicine read a paper on the surgical treatment of cerebral hemorrhage in 2 cases. In the first case left facial paralysis, the Babinski reflex (right) and lateral left hemianopsia were present. The cerebrospinal fluid gave negative Wassermann and Kahn reactions. After some days the patient had hallucinations and did not answer questions. The pupils were dilated, they reacted weakly to light and the fundus of the eye showed stasis of the optic papilla. The patient became comatose and they decided to intervene to save his life.

Under local anesthesia with the patient in a half sitting position a vertical temporal incision was made and the cranium trephined. The dura mater appeared tense and violet hued. The opening was enlarged by means of a gouge and first the dura mater and then the temporal convolutions were incised revealing a hemorrhagic focus the size of a nectarine, which was removed by aspiration and by means of a curet. After hemostasis the dura mater, the aponeurosis and the skin were sutured. Some hours after the operation the patient recovered consciousness. After three days all pathologic symptoms had disappeared except the hemianopsia. After a fortnight the patient was cured except for a slight reduction in the field of vision of the left eye. The same brilliant result was obtained in the second case.

This operation cannot be performed in all cases of cerebral hemorrhage, in many cases one does not find only one hemorrhagic focus a hematoma, but many which are not determined by vascular rupture but by a massive erythrodiapedesis. Lhermitte and Guillaume believe that ventriculography is not always indicated to diagnose the foci. This examination is indicated only in cases in which the neurologic signs do not point to the seat of the hemorrhagic foci. An enlarged trepanation is not indicated on account of the extreme sensibility to traumatism of patients with intracerebral hematomas especially as an enlarged opening by means of the gouge is sufficient for this operation.

## Deaths

**Clinton Hart Merriam**, Berkeley, Calif., College of Physicians and Surgeons, medical department of Columbia College, New York, 1879, founder and director for many years of the United States Biological Survey, conducted biologic and ethnologic explorations in the Far West, in 1931 was awarded a Roosevelt medal for distinguished service in the advancement of the study of natural history, past president of the American Ornithologists Union, American Society of Naturalists, the Biological Society of Washington, the Anthropological Society of Washington and the American Society of Mammalogists, member of the National Academy of Sciences, American Philosophical Society and the Washington Academy of Sciences, foreign member of the Zoological Society of London, author of "The Birds of Connecticut," "Mammals of the Adirondacks" and "Geographic Distribution of Life in North America" and many other books, aged 86, died, March 19.

**George J. Newgarden** ♂ Lieutenant Colonel, U S Army, retired, Washington, D C., Jefferson Medical College of Philadelphia, 1889, entered the medical corps of the U S Army as an assistant surgeon in November 1892, was commissioned a major Nov 23, 1905, retired April 24, 1907 for disability in line of duty, returned to active duty May 2, 1917 and served until 1919, retired as a lieutenant colonel under the Act of June 21, 1930, veteran of the Spanish-American War and World War I, aged 77, died, March 25, in the Walter Reed General Hospital.

**Richard Joseph Coyne**, Philadelphia, Hahnemann Medical College and Hospital of Philadelphia, 1924, member of the Medical Society of the State of Pennsylvania, from 1927 to 1931 assistant in laryngology and rhinology, from 1931 to 1933 instructor in laryngology and rhinology and from 1933 to 1936 demonstrator in laryngology and rhinology at his alma mater, examining physician for draft board number 63, served during World War I, aged 44, died, March 25.

**Aspinwall Judd** ♂ New York, Columbia University College of Physicians and Surgeons, New York, 1896, formerly adjunct professor of surgery at the New York Post-Graduate Medical School, at one time attending surgeon at the Lutheran Hospital of Manhattan, formerly affiliated with the Broad Street Hospital, now known as the Downtown Hospital, and was on the staff of the Bellevue Hospital, aged 74, died, March 17, of coronary embolism.

**George Thomas Conley**, Williamson, W Va., Louisville (Ky) and Hospital Medical College, 1908, member of the West Virginia State Medical Association, fellow of the American College of Surgeons, past president and secretary of the Mingo County Medical Society, formerly member and president of the school board, aged 60, surgeon and co-founder of the Williamson Memorial Hospital, where he died, March 20, of carcinoma.

**William Humes Houston** ♂ Lieutenant Colonel, U S Army, retired, Key West, Fla., University of Maryland School of Medicine, Baltimore, 1900, an Affiliate Fellow of the American Medical Association, entered the medical corps of the U S Army in 1920, rose through the various grades to that of lieutenant colonel in 1937, when he retired for disability in line of duty, served during World War I, aged 66, died, March 20.

**Charles Emerson Townsend** ♂ Newburgh, N Y., Bellevue Hospital Medical College, New York, 1892, fellow of the American College of Surgeons, president of the board of managers, consulting surgeon and formerly chief surgeon and chief of the hospital staff of St Luke's Hospital, consulting surgeon, Highland Hospital, Beacon, and the Goshen (N Y) Hospital, aged 71, died, March 16, of agranulocytic angina.

**Maurice Lincoln Fisher** ♂ Mansfield, Ohio, Yale University School of Medicine, New Haven, Conn., 1924, fellow of the American College of Surgeons, member of the American Association for Thoracic Surgery and the American College of Chest Physicians, formerly medical director of tuberculosis work in Richland County, chest consultant, Mansfield General Hospital, aged 41, died, March 18.

**Victor Augustus Reed** ♂ Lawrence, Mass., Harvard Medical School, Boston, 1897, formerly medical examiner for the fifth Essex district, served as a line officer in the National Guard in 1902 and later as a captain in the medical corps at Fort Williams, Portland, Maine, on the staff of the Lawrence

General Hospital, aged 73, died, February 24, at his home in Methuen of coronary thrombosis.

**Harry Z. Hibshman** ♂ Philadelphia, Medico-Chirurgical College of Philadelphia, 1908, member and past president of the American Proctologic Society, fellow of the American College of Surgeons, professor of proctology at the Temple University School of Medicine, proctologist, Temple University Hospital, consulting proctologist, Northeastern Hospital, aged 62, died, March 17.

**Charles Jules Lowen**, Denver, Long Island College Hospital, Brooklyn, 1909, member of the Colorado State Medical Society, fellow of the American College of Surgeons, formerly instructor in surgery at the University of Colorado School of Medicine, on the staffs of St Joseph's Hospital and the National Jewish Hospital, aged 56, died, March 26, of coronary thrombosis.

**Baylis Haynsworth Earle** ♂ Passed Assistant Surgeon, U S Public Health Service, Greenville, S C., Medical College of the State of South Carolina, Charleston, 1892, entered the U S Public Health Service as an assistant surgeon, April 9, 1900 and became a passed assistant surgeon July 26, 1906, formerly county health commissioner, aged 72, died, March 31.

**Edgar Elliott Findlay** ♂ Passed Assistant Surgeon, U S Public Health Service, Ashland, Ky., Ohio State University College of Medicine, Columbus, 1935, was appointed an assistant surgeon in the U S Public Health Service, April 1, 1937 and a passed assistant surgeon, April 1, 1940, aged 31, died, March 28, of asphyxiation.

**Francis Holmes Matthews** ♂ Liberty, Mo., University Medical College of Kansas City, 1900, past president and secretary of the Clay County Medical Society, past president and vice president of the state board of health, physician in charge of the Missouri Odd Fellows Home Hospital, aged 75, died, March 23.

**Frank R. England**, Montreal, Que., Canada, University of Bishop College Faculty of Medicine, Montreal, 1885, fellow of the American College of Surgeons, formerly professor of surgery at his alma mater, consulting surgeon, Montreal General Hospital and the Woman's General Hospital, Westmount, aged 79, died, March 9.

**James Henry Cook**, Quincy, Mass., Tufts College Medical School, Boston, 1910, member of the Massachusetts Medical Society, fellow of the American College of Surgeons, served during World War I, on the staff of the Quincy City Hospital, aged 58, died in March at East Hampstead, N H, of heart disease.

**George Romain Stalter**, Knoxville, Iowa, University of Buffalo School of Medicine, 1912, member of the American Psychiatric Association, served during World War I, for many years associated with the Veterans Administration, manager of the Veterans Administration Facility, aged 52, died in March.

**Ernest Albert Jenkinson**, Sioux City, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903, member of the Iowa State Medical Society, fellow of the American College of Surgeons, on the staff of St Vincent's Hospital, aged 70, died, March 17.

**David Solomon Grim** ♂ Millbach, Pa., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900, past president of the Berks County Medical Society, served during World War I, aged 69, for many years on the staff of St Joseph's Hospital, Reading, where he died, March 10.

**Abram F. Lumpkin**, Amarillo, Texas, University of Texas School of Medicine, Galveston, 1896, member of the State Medical Association of Texas, fellow of the American College of Surgeons, on the staffs of St Anthony's Hospital and the Northwest Texas Hospital, aged 67, died, March 16.

**Elliott Washburn**, Brooklyn, Harvard Medical School, Boston, 1892, formerly chairman of the Taunton (Mass.) board of health, at one time on the staff of the Morton Hospital, Taunton, formerly superintendent of the Rutland (Vt.) State Hospital, aged 72, died, February 17.

**John S. Hart**, Toronto, Ont., Canada, Victoria University Medical Department, Coburg, 1888, University of Toronto Faculty of Medicine, 1889, for many years on the staff of the Toronto Hospital for Incurables and the Toronto Western Hospital, aged 81, died, March 30.

**Cicero Jackson Connor** ♂ Corpus Christi, Texas, Worth School of Medicine, Medical Department of Texas

Christian University Fort Worth 1917, aged 46 died in March at the Brackenridge Hospital, Austin of injuries received in an airplane accident

Oscar Wilhelm Tuhsalo, Atlanta, Ga Rush Medical College, Chicago, 1917, member of the Medical Association of Georgia, served during World War I, aged 49, on the staff of the Georgia Baptist Hospital, where he died, March 14 of acute hepatitis

Charles Ryan \* Des Moines, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1909, fellow of the American College of Surgeons attending surgeon, Iowa Lutheran Hospital, aged 69, died March 8

Thomas Jefferson Halsey \* Butler, Mo., University of Nashville (Tenn) Medical Department 1893, Vanderbilt University School of Medicine, Nashville, Tenn, 1893, past president of the Bates County Medical Society, aged 74, died, February 26

James Augustus McCloskey \* Major, M C, U S Army, San Antonio Texas, St Louis University School of Medicine, 1933, became a first lieutenant in the medical reserve corps of the U S Army June 6 1933 and was on active duty from Jan 22, 1935 to Jan 29, 1936, was commissioned a first lieutenant in the medical corps of the U S Army Jan 30, 1936, a captain Jan 22, 1938 and major Dec 29, 1941, aged 32, was killed in action in the Philippine Islands, March 26

Richard Crawford Haynes, Wedo-  
vee Ala., Chattanooga (Tenn) Medical College 1906 member of the Medical Association of the State of Alabama, aged 64, died, March 21, in the Knight Sanatorium, Roanoke, of a penetrating bullet wound of the chest

Franklin Sheldon Ruttan, Woodstock, Ont, Canada, Queen's University Faculty of Medicine Kingston, 1893, served with the Royal Canadian Army Medical Corps during World War I, medical officer of health of Woodstock, died January 12

Morris Wayne Bottorf \* Kalispell, Mont Hahnemann Medical College and Hospital, Chicago, 1895, past president of the Flathead County Medical Society, on the staff of the Kalispell General Hospital aged 70, died, March 16, of heart disease

Garrett Mack Van Ausdall, New London, Iowa, Medical College of Indiana, Indianapolis 1884, member of the Iowa State Medical Society, bank president, past president of the Henry County Medical Society aged 83, died, February 27

Edward F Mikeska \* Taylor, Texas, University of Texas School of Medicine, Galveston, 1910 medical director of Dr Floeckinger's Sanitarium on the staff of the Stromberg Clinic and Hospital, aged 56, died, March 26, of coronary occlusion

Herman Burgess Cole, Redwood Falls, Minn., University of Buffalo School of Medicine 1896 member of the Minnesota State Medical Association, aged 70, died, March 29 of diabetes mellitus, cerebral hemorrhage and arteriosclerosis

Harry M Greenwald \* Brooklyn University and Bellevue Hospital Medical College New York 1910, member of the American Academy of Pediatrics, on the staff of the Israel-Zion Hospital aged 51, died, March 13, of hypertension

Albertus Adair Moore \* New York, University of the South Medical Department Sewanee, Tenn 1895 Medical College of the State of South Carolina, Charleston 1896, served during World War I, aged 67, died, March 23

Robert Bailey, St Clair Shores Mich., University of Michigan Homeopathic Medical School Ann Arbor 1911 member of the Michigan State Medical Society, veteran of the Spanish-American War, aged 72 died in March

Orren William Wyatt \* Manning Iowa University of Nebraska College of Medicine Omaha 1909 past president of the Carroll County Medical Society, medical director of the Wyatt Memorial Hospital aged 61 died February 3

Fred Norton Blanchard, Detroit, Detroit College of Medicine, 1903, member of the Michigan State Medical Society, served during World War I aged 63, on the staff of the Harper Hospital, where he died, March 3

John Thomas Stringer \* Medical Inspector, Commander, U S Navy, University of Maryland School of Medicine, Baltimore, 1915, was commissioned in the navy Dec 29, 1917 aged 54, died, March 6, in Baltimore

Caroline Jane Young High, Woodside, N Y, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897, aged 77, died, March 10, in the James W Sheldon Memorial Hospital, Albion, Mich

John Harvey Hudson, Vanceboro, N C, College of Physicians and Surgeons, Baltimore, 1907, aged 64, died in March at St Luke's Hospital, New Bern, of injuries received when he was struck by an automobile

William Elbert Cravens, Lubbock, Texas, Kentucky School of Medicine, Louisville, 1892, member of the State Medical Association of Texas, on the staff of the West Texas Hospital, aged 71, died, March 18

George A Bell, Los Angeles Saginaw (Mich) Valley Medical College, 1903, formerly coroner of Saginaw County, Mich, and Saginaw County physician, aged 66, died, April 15, of carcinoma of the intestine

Walter Clay Dickey, Memphis, Texas, University of Texas School of Medicine, Galveston, 1906, for many years bank president, aged 59, died March 6, in the Baylor University Hospital Dallas

John F Cooke, Smiths Grove, Ky, University of Louisville (Ky) Medical Department, 1888 for many years bank president formerly member of the county board of education, aged 77, died March 29

Joseph Gauvreau, Montreal Que, Canada, Laval University Faculty of Medicine, Quebec, 1898 formerly registrar, College of Physicians and Surgeons of the Province of Quebec, aged 71, died in March

George S Deibert, Wescosville, Pa Temple University School of Medicine Philadelphia 1910, served during World War I, aged 65 died, March 23 in the U S Naval Hospital Philadelphia

James E Douglass, Tarpon Springs Fla College of Physicians and Surgeons, Baltimore 1873, formerly mayor, aged 90, died, March 1, of chronic myocarditis and valvular heart disease

G D Dorrough, Quitman, Ga Atlanta Medical College 1895, member of the Medical Association of Georgia, aged 76, died, March 16, of acute dilatation of the heart and chronic nephritis

Robert Dickson Ferguson, Pilot Mound Man, Canada, Manitoba Medical College 1897, served during World War I formerly mayor and medical health officer, aged 75, died, March 2

Harry Evans Pelle, Louisville Ky, Hospital College of Medicine, Louisville, 1877, member of the Kentucky State Medical Association, aged 86, died March 4, of myocardial failure

B Wade Baker, Grafton, Ohio Homeopathic Hospital College, Cleveland 1882, aged 85 died February 23 of carcinoma of the prostate

Alfred P Gray, Philadelphia Jefferson Medical College of Philadelphia 1896 aged 70, died March 27 of a self-inflicted bullet wound

Lewis De Moss Wolfe, Columbus Ohio Ohio Medical University, Columbus 1902, aged 66 died February 4

George Fierheller, Toronto Ont. Canada Trinity Medical College Toronto 1884 aged 81 died February 8

Albert M West, Spirit Lake Iowa Chicago Homeopathic Medical College 1904 aged 82 died January 15

Frank C Britton Greenville Tenn Chattanooga Medical College 1893 aged 76 died February 7

# KILLED IN ACTION

JAMES A. MCCLOSKEY, MAJOR M C,  
U S ARMY, 1909-1942

## Bureau of Investigation

### DIAPLEX DUPED DIABETICS

#### Frederick Dugdale, M D, Meets Expert Witnesses for the U S Post Office

For some years "Diaplex," an alleged diabetes cure, was sold through the mails from Denver by the Diaplex Laboratories and from Portland, Maine, by Frederick Dugdale, M D, who was known as "Chief Medical Advisor" [sic] of the Denver concern. Dugdale obtained a diploma in 1903 from the Baltimore Medical College and licenses to practice in Massachusetts and Maine.

Dugdale's Massachusetts license was revoked in 1929 for "gross misconduct in the practice of his profession." It was reported that this action was based on the charge that he had treated a woman in the last stages of cancer with the nostrum put out for that condition by William F Koch of Detroit and virtually promised that it would cure her. When the Lowell, Mass., *Sun* published a considerable article on this case, Dugdale sued that paper for libel and demanded \$50,000 damages. After hearing the evidence the jury in less than two hours brought in a verdict in favor of the *Sun*.

In the same field Dugdale was said to have been interested in the "Hovide" cancer fakery and also to have put out a "cancer cure" of his own, known as "The Dugdale Treatment for Malignant Growths," as well as a "rheumatism cure," besides advertising himself as a "Boston Specialist" in "skin, blood and nervous diseases." In addition, he was at times associated with such "twilight zone" organizations—to which so many quacks and faddists have belonged—as the "Allied Medical Associations of America," the "Medical Society of the United States" and the "American Association for Medico-Physical Research." The latter was an outgrowth of the "American Association for Spondylotherapy," organized by the outstanding quack of the century, Albert Abrams, of whom Dugdale was a disciple. All of this serves as excellent background for the promotion of a "cure" for diabetes.

After an investigation, the Post Office Department on Oct 19, 1940 ordered the Diaplex Laboratories and its general sales manager, H W Pierce, both of Denver, and Frederick Dugdale as "Chief Medical Advisor" to show cause on November 26 of that year why a fraud order should not be issued to debar them and their "treatment" from the mails because of what the Post Office charged were false and fraudulent pretenses, representations and promises. Among these were that Diaplex would permanently cure diabetes regardless of the age of the user or the severity of the case, would enable the user to discontinue taking insulin, would clear the urine of sugar and result in "a gradual, lasting building-up of the body glucose tolerance", would, through its "mineral and vitamin content," restore the islands of Langerhans so that they would secrete a normal supply of insulin, and that all users of Diaplex would obtain results identical with or similar to those described in the alleged testimonials in the literature.

After two postponements requested by the defendants' attorney, the hearing was held on December 13. A government chemist testified that his analysis of Diaplex had shown it to be a mixture of sodium, potassium, calcium, chloride, sulfate, phosphate and traces of iron, manganese, aluminum, silica and iodine. Apparently these chemicals were found in the ash of saltbush, the plant from which, Pierce testified, his nostrum was made and which government chemists confirmed in another examination. Also appearing for the government was Dr Maurice Protas of Washington, D C, who specializes in the treatment of diabetes and lectures on that disease at George Washington University School of Medicine. He testified that diabetes mellitus is a metabolic disease in which the pancreas is involved, wherein there is a definite lack of insulin due to failure of the islands of Langerhans to produce the insulin hormone which is vital to the blood. He further stated that diabetes may be caused, among other things, by any malignancy which attacks the tissues and spreads to the pancreas, with the result that the insulin secreting cells may be destroyed. He showed that in the severe types of diabetes the patient

must be given insulin injections, dietary restrictions and other individualized treatment, and that in milder cases the patient requires a restricted diet as to sugars and starches and some times needs insulin. Dr Protas had tested Diaplex on three diabetic patients and found from careful clinical records that they made no progress whatever in six weeks—a period in which, he stated, a definite improvement would show, if ever. Dr Protas offered further testimony which refuted the various claims and representations made for Diaplex.

Dr Dugdale himself as one of the defendants was obliged to admit that some of the representations could not be scientifically substantiated. He further admitted that he had not made any physical examination whatever of the twenty five or so persons whom he cited as diabetic who allegedly had been benefited by taking Diaplex, nor had he submitted them to laboratory tests.

The other defendant, H W Pierce of Denver, said to be sole owner of the Diaplex business, also was put on the witness stand. He testified that around 1906 a neighbor suggested the use of a certain herb for the treatment of Pierce's brother, an alleged diabetic, and that he, the witness, later identified the herb as saltbush and obtained it from some sheepmen. Although Pierce claimed that by the use of the saltbush his brother was cured of diabetes, he admitted that two physicians who had previously treated the patient had diagnosed his disease as dropsy. Pierce further contended that he knew of various persons whose diabetic condition had been helped by Diaplex, including himself, but he refused to submit to a scientific test to prove his freedom from the disease.

In 1930, according to Pierce, he began marketing the product, successively naming it "American Beauty Tea," "American Beauty Beverage" and "Diaplex." In spite of the "laboratory" part of his firm name he acknowledged that he did not maintain a laboratory and had no employees. Further testimony from him showed that, though he had read some books on diabetes, he had never found one in which saltbush was recommended for that condition. In fact, since neither defendant was able to present any evidence that saltbush was a cure for diabetes, their promotion of Diaplex was found to constitute a swindle on the public. Accordingly their business was debarred from the mails by a fraud order issued on March 27, 1941 against the names Diaplex, Diaplex Laboratories, H W Pierce, Dr Frederick Dugdale and their officers and agents. Two days later a separate fraud order was issued against Frederick Dugdale, who represented the eastern office of the Denver concern.

Previous mention has been made of the fact that Dugdale once was a disciple of the late Albert Abrams of "electronic reactions" notoriety. It is interesting to note that at the hearing of the case that the Post Office brought against him part of the government's evidence was a printed circular, "The Successful Treatment of Diabetes with Diaplex," which recommended the use of Diaplex in connection with "electronic devices." And yet such contraptions originally were represented by their promoters as self sufficient for treatment of disease without the use of any drugs.

Between 1935 and 1940 another government agency, the Food and Drug Administration, seized consignments of Diaplex in interstate commerce in at least 9 cases on record, on the ground that the labels bore fraudulent representations. In 6 of the cases no one put up a defense or claimed the property, and the court ordered it confiscated. In 1 instance an Idaho consignor having consented to the entry of a decree of condemnation was permitted to claim the consignment by promising under oath that it would be relabeled in compliance with the law. In the 2 remaining instances, which involved shipments of Diaplex from Denver to California and Idaho and cited H W Pierce and W J Predmore of Denver as defendants, the cases were tried together before a jury. Here it is worth reprinting a Current Comment which appeared in THE JOURNAL Jul 4 1936, page 42, under the heading "Doctors and Diaplex."

"In a recent trial the federal government was defeated in its attempt to prove one Horace Wayne Pierce manufacturer and shipper of a herb tea called 'Diaplex,' guilty of fraud under the criminal clause of the Food and Drugs Act. Diaplex is dried leaves and stems of *Atriplex canescens* (sagebrush) offered as a specific for diabetes. The advertising campaign

the dangers of insulin and dwells on the simplicity of taking Diaplex. The government lost its case principally because of the premature enthusiasm of a physician for the nostrum. As told in a brief summary of the case issued by the United States Department of Agriculture, the government contended that the falsity of the claims made for Diaplex as a remedy for treating diabetes was fully proved. The breakdown in the government testimony came when two witnesses—one a doctor and the other a layman—admitted the writing of complimentary and optimistic letters to the manufacturer. Both these witnesses testified nevertheless that they had been misled, as the herb tea turned out to be worthless in their later experience. At the trial Pierce claimed that he depended on these letters as expressions of opinion from persons competent to judge the effects of his treatment. In the face of this testimony, the jury was not convinced of the fraudulent intent, which, under the law, must be shown in all criminal cases involving curative claims for medicines. The testimony of physicians called by the government that Diaplex could not affect the course of diabetes was entirely nullified by the careless endorsement of one physician. Endorsements given by physicians to 'patent medicine' vendors, either carelessly or wilfully, are invariably distorted into bait for the uncritical patient as a means of luring him away from proved methods of treatment. The case of Diaplex should serve as a warning to the physician against haste in judgment of therapeutic results. The difficulty of evaluating remedies for arthritis, diabetes, nephritis, hypertension and similar chronic conditions should be realized. The lack of suitable controls is apparent in all these hasty enthusiasms which lead doctors into writing or voicing commendation before time has truly tested the results. Then, like the ghost in Hamlet, their testimonials come back in after years to haunt them."

## SOME MISCELLANEOUS MEDICAL FRAUDS

### A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

**Adams Products Company**—From Adams N. Y. and Montreal Canada a Frederick Godfrey sold a hair treatment under the Renair name and sometimes operated as the Frederick Godfrey Company. Some of his advertising described him as a hair specialist famous in England, Australia and New Zealand and now in Canada and again he called himself 'a young English research worker in hair and scalp conditions' and claimed that sworn statements and actual photographs clearly prove the success of his process. His advertising was directed toward people wholly or partially bald or whose hair is thinning rapidly. Finally the Post Office looked into his activities and charged that he was falsely and fraudulently representing that his Renair Process which included Renair Hair Lotion, Renair Lotion No. 2 and Renair Pomade and instructions concerning massage would when used as directed stop hair from falling and prevent baldness in all cases except those due to the atrophy of old age and produce numerous other results. According to the Post Office memorandum on this case Godfrey had operated under his personal name and that of the Frederick Godfrey Company up to Sept. 30, 1939 on which date the Post Office had called on him to show cause why a fraud order should not be issued against his name and that of the Frederick Godfrey Company for perpetrating a fraud on the public through the mails. On December 30 Godfrey filed an affidavit with the Post Office in which he promised to abandon the business and agreed that the postmaster at Adams N. Y. should be directed to return to senders all mail addressed to Godfrey or his concern and mark it 'Out of Business' or otherwise to dispose of it according to the postal regulations. Subsequent investigation by the Post Office however revealed that Godfrey did not actually go out of business but continued his operations after adopting a new name the Adams Products Company and under this trade style circularized former customers telling them in effect that the formulas and rights for the Renair Process had been procured by the new company from Frederick Godfrey and that future orders and remittances should be addressed to the new name. As this ruse was a transparent one the Post Office on Jan. 30, 1941 ordered the Adams Products Company to show cause on February 17 why a fraud order should not be issued against it. After a continuance had been granted the defendant he finally appeared with one of his attorneys at the hearing set for March 3. The only explanation that he offered for the continuance of the business under a new name was that an attorney he had previously employed had advised him that this action would not violate the terms of the affidavit that he had signed promising to go out of business. He further testified that he had revised his circular matter and believed that he had removed therefrom all objectionable statements. There also appeared at the hearing three witnesses for the government including two physicians who specialize in dermatology and a chemist

connected with the Food and Drug Administration. The latter testified that he had found the Renair Hair Lotion to contain 0.017 Gm. of sulfuric acid and 0.21 grain of quinine sulfate in each 100 cc. The Hair Lotion No. 2 he testified contained 58 per cent of alcohol, 11 grams of resorcinol and a small amount of capsaicin in each 100 cc. In the Pomade he found 29 per cent of betanaphthol and 2 per cent of a volatile oil resembling cedar leaf oil. The two dermatologists who appeared as government witnesses testified that Renair Pomade when applied to the scalp as directed would have a fairly strong counterirritant and mildly antiseptic action and that the Hair Lotion No. 2 would be mildly antipruritic antiseptic and irritant. Their further testimony however showed that these products would have practically no effect on falling hair and baldness. It was also shown at the hearing that Godfrey had requested that he again be permitted to file an affidavit agreeing to discontinue this business on the ground that he had never intended to violate the provisions of the previous affidavit. As this however was exactly what he had done the Post Office did not consider it expedient to grant his second request and on May 6, 1941 issued a fraud order against the Adams Products Company and its officers and agents.

**R. F. Vestvold**—Under this assumed name one Rolf Frank Kristiansen of Haverford Pa. promoted through the mails three devices known as 'The Photo-Electric Dilator', 'The Flexible G. U. Heater' and 'The Adjustable Intermittent'. For the dilator he claimed that it was in use by over 6,000 physicians throughout the world and could be employed by any one physician or layman to ameliorate the ravages of Prostate Gland Trouble, Piles, Pruritis [sic] Ani and Constipation etc. Luminous Infra-red rays does it \$3.75 Postpaid. Inquirers received a mimeographed circular containing testimonials alleged to have been written by physicians in various parts of the country and abroad. The mechanism consisted of a large rectal dilator connected to an electrical cord with an electric socket attached for the insertion of a light globe. The dilator itself consisted of a glass tube about four inches long and three-quarters of an inch in diameter. A scientific test made of the maximum temperature reached by the instrument when used according to the directions showed 104 degrees Fahrenheit. At the hearing of this case an expert medical witness testified for the government that hemorrhoids, enlarged prostate, pelvic abscesses, cystitis, gonorrhea and some kindred disorders are all due to different causes which should be treated accordingly and hence devices such as the Photo-Electric Dilator would give little if any relief in general. The Adjustable Intermittent was shown to consist of an electrical intermittent which when connected to the house current along with the dilator would result in the intermittent flow of current to the latter. According to the expert medical testimony the combination of these devices would not afford effective passive massage action in the treatment of prostatic conditions as represented beyond the interruption of the steady flow of current and the resultant heat produced thereby. The Flexible G. U. Heater according to the Post Office memorandum was found to consist of a rubber catheter about two feet long containing a metal heating element. It was to be connected to the regular house current by means of an electric plug and switch. Scientific tests made of this device disclosed that when used according to directions it would reach a maximum temperature of 107.6 degrees Fahrenheit within five minutes after the current was turned on. It was represented as a cure for such conditions as urethritis, strictures, urine retention, gonorrheal infections and kindred disorders. The expert medical witness testified that there is no known single curative agent for any of these ailments but that the employment of this device might in some instances offer minor temporary relief. Nothing more could be expected of it and in fact its use might prove dangerous in the hands of a layman. It was further shown that Kristiansen (Vestvold) was not a physician but a plumber by trade. Subsequent to the hearing he offered to revise his advertising literature to remove any objectionable claims but as the Post Office found from the evidence that his scheme constituted a swindle on the public through the mails a fraud order was issued on April 26, 1941 against the name of R. F. Vestvold.

**W. C. Foster**—This person conducted a mail order business from a postoffice box in Santa Monica Calif. describing himself as president of his unnamed firm and also as Distributor of Private Pharmaceutical Formula. He put out O. A. Capsules which he puffing as 'The Newest and Greatest Contribution Medical Science Has to Offer' but there followed the simple denouement that it consisted of acidophilus yeast! A chemist and a microanalyst who examined the product for the government however reported that a positive test made for the presence of yeast cells in O. A. Capsules failed to detect any of this substance although the label declared that they consisted of acidophilus yeast and ovarian and prostatic extracts. They did report finding in each capsule crystalline milk sugar, alfalfa leaf tissues, granular animal tissues, corn starch and rice bran. This mixture was represented to enable the user to attain and retain a strong healthy sexual system regardless of his age or physical condition and to rebuild and revitalize the parts of the glandular system which are necessary for smooth powerful active sexual system with almost instant results. At the hearing of the case these claims were refuted by the physician who testified for the government that sexual debility is due to many causes associated with various systemic diseases and conditions such as tuberculosis, cancer, venereal disorders, anemia and certain injuries to the sexual structure and that sexual impotence may also result from such factors as psychic conditions, emotional changes, senility and financial and family worries. Hence every case of sexual debility would have to be studied as to its cause and treated accordingly. This witness further showed that the product in question would not and could not cause every person to attain and retain a strong healthy sexual system and that it contained nothing which would overcome any or all of the various factors causing sexual debility. Other evidence was presented to show that neither Mr. Foster nor any one else associated with the business had any medical training and that in fact Foster formerly had been employed as a coal worker. Foster put up no defense and on Sep. 17, 1941 the Post Office issued a fraud order declaring him and his business from the mail.

### WARNING ON USE OF PHENOL-CAMPHOR IN CASES OF "ATHLETE'S FOOT"

To the Editor —I was pleased to note in the current issue of *THE JOURNAL* your comments on phenol-camphor for "athlete's foot," especially since it warns again that the phenol-camphor preparation should not be applied to the wet skin. Our previous experience with phenol-camphor mixtures caused us to be a little bit dubious about the clinical note which appeared in *THE JOURNAL* of Dec 6, 1941, but we did not immediately begin any investigations of these preparations and, as a matter of fact, did not perform any experiments until a case came to our attention which resulted from the appearance of an item in *Science Supplement* of Dec 19, 1941. In the item in *Science Supplement* it states "The remedy consists of a mixture of three parts phenol and one part camphor which can be prepared by any pharmacist." The injury which came to our attention, as I said, was the result of a person's noting this item and having a pharmacist prepare such a preparation and subsequently using it. The material was applied to a fairly large area on the leg near the ankle. A necrotic area developed which required several weeks to heal. This was the situation we feared when we read the rather peculiar combination of sentences in the second paragraph of the clinical note which appeared in *THE JOURNAL*. The last sentence of this paragraph states, as you will recall, "Experiments indicate that the ingredients may be mixed in the proportion of 3 parts phenol and 1 part camphor," which is followed by a paragraph, the first sentence of which states "The mixture is nonirritating to the skin and may be painted between the toes several times a day."

Soon after this case came to our attention we began some experiments, using rabbits as the test animal, since it is quite well recognized that rabbit skin responds very much the same as that of human skin to many types of preparations. Our experiments were finished a few days ago and we had just been debating the best possible manner of presenting this information to the public in order to prevent further serious injuries when we noticed the editorial comment in *THE JOURNAL*. Since you have stated in it that a number of investigations are now being conducted to determine the extent of the causticity of the phenol-camphor mixture and its possible benefits and dangers, we thought you might be interested in the results of our investigations. Briefly summarized, they are as follows:

1 Three preparations were prepared, namely a National Formulary VI preparation composed of 6 parts of camphor, 3 parts of phenol and 1 part of liquid petrolatum.

2 A 1 to 1 mixture of camphor and phenol without petrolatum.

3 One part of camphor plus 3 parts of phenol without petrolatum.

These preparations were each applied to a clipped area of skin of the rabbit and in each instance the National Formulary preparation was used on one area while one of the other two preparations was used on a different area of the same animal. The applications were made twice a day and the largest number of total applications was seven for any one of the three preparations. In order to simulate the sock and the shoe, we used dry gauze covered by adhesive tape to cover the areas. In the case of the National Formulary preparation applied to dry areas, there was only very slight irritation and very slight

erythema, if one could consider it positive at all. With the 1 to 1 preparation the irritation and erythema were also slight but definitely more noticeable than with the National Formulary preparation. When the same two preparations were used on areas that had been moistened to such an extent as to resemble mild perspiration, the effects were definitely more noticeable, even in the case of the National Formulary preparation, and in that of the 1 to 1 mixture after the second application the area was discolored black and after the fourth application there was a severe burn with a necrotic eschar. When the mixture of 1 part camphor and 3 parts phenol was applied to the dry skin, there was a severe burn even after the first and particularly after the second application, followed by a necrotic eschar. When the area was wetted prior to application of the mixture of 1 part camphor and 3 parts phenol, a condition arose similar to that when it was applied to the dry skin but even more severe.

We feel that further emphasis should be given by some means to the injuries that may result from the caustic nature of this type of preparation, particularly the one containing 3 parts phenol and 1 part camphor. A further warning would be advisable by *THE JOURNAL*, and I feel that warning notes should also be published in those journals which have reprinted this information, particularly *Science*, *Readers' Digest* and some of the drug trade journals. I shall call this to their attention by sending them copies of this letter.

HERBERT O. CALVERY, PH.D.

Chief, Division of Pharmacology,  
Food and Drug Administration,  
Washington, D. C.

### DOES DIABETES PREDISPOSE TO PYOGENIC SKIN INFECTIONS?

To the Editor —In the article by J. R. Williams "Does Diabetes Mellitus Predispose the Patient to the Pyogenic Skin Infections?" (*THE JOURNAL*, April 18, p. 1357) the author concludes that pyogenic skin infections occur no more frequently in diabetic than in nondiabetic persons, but the statistics presented by him do not bear out his point. In one of the hospitals studied by him 330 diabetic patients were admitted during the years 1938, 1939 and 1940. Eight of these had boils or carbuncles, which gives a percentage of 2.4. During this same period there were 26,879 nondiabetic admissions, among which there were 166 boils or carbuncles. This gives an incidence of 0.6 per cent. In other words, according to the author's figures boils or carbuncles were four times as common among diabetic as among nondiabetic patients. In the other hospital studied, one is unable to make this calculation because the number of patients with diabetes is not given. Similarly, in a study of 2,130 office patients the author does not state how many diabetic patients were in the group. Before concluding that there is no relationship between diabetes and pyogenic infections of the skin, one would have to study a series of patients in whom the disease was not under control, and the advent of insulin such a series would be difficult to obtain. Whenever I see a boil or a carbuncle I make it a point to test the urine for sugar, and it is my impression that diabetics find a little more frequently in these patients than in normals. I agree with Dr. Williams that if the disease is being controlled the diabetic patient is not in much danger from boils or carbuncles, but I still believe that he is in a little more danger than a normal person.

FREDERICK C. HILL, M.D.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Liability for Prenatal Injuries to Infants**—In 2 cases decided within a month of each other the courts of Pennsylvania and New Jersey passed on the question of whether or not an infant could recover damages for injuries sustained prior to its birth. Opposite conclusions were reached.

In the first case, decided by the Supreme Court of Pennsylvania, no facts were stated in the decision. The court merely said that the question had never before been presented to an appellate court in Pennsylvania, cited four decisions from other jurisdictions denying a right of recovery to the infant and concluded that there was no warrant for holding, independent of statute, that a cause of action for prenatal injuries to a child accrues at birth. The Supreme Court of Pennsylvania admitted, however, that "it is true that the unity of mother and child has been relaxed in modern times and that today for some beneficial purposes a child en ventre sa mere is considered as born."

In the New Jersey case the circuit court of Middlesex County exhaustively discussed the principles of law involved and cited many cases that have been decided on the subject. The real plaintiff in the case was a 5 year old boy. He filed suit by his next friend, for damages, alleging that, prior to his birth, his mother had gone to the defendant physician for medical attention and, because of the physician's negligence in diagnosis and the administration of roentgen treatments, the plaintiff was born a microcephalic and an idiot, without skeletal structure, sight, speech, hearing or the power of locomotion. The defendant filed a motion to dismiss the plaintiff's complaint on the ground that an infant had no right to maintain an action for injuries sustained while en ventre sa mere.

The court said that the law has long recognized that, for all purposes beneficial to the infant after birth, a child en ventre sa mere is to be considered as born and that a right of action to recover for prenatal injuries is certainly for the child's benefit. The perfect answer and unanswerable argument, the court said, in the determination of the issue here presented, a problem in the law of torts, is the application of the criminal law in offenses committed against an infant en ventre sa mere. Assault and battery is an integral part of murder. Murder by force cannot be committed without there being an assault and battery. If it is an offense under the criminal law to assault and batter a child en ventre sa mere, that crime ripening into murder if the child is born alive and later dies as the result of its prenatal injuries, it in all justice and logic must be said that the child has a right of action after its birth for prenatal injuries inflicted on it by the wrongdoer. Assuming as it must be assumed, the court continued, that an indictment for assault and battery would lie, certainly a right of action sounding in damages for the tort should be allowed. While it is true that the majority of the decided cases are against the right of recovery for an alleged tort committed against a child yet unborn the court pointedly remarked that in its opinion the weight of authority holds for the recovery. The well-being and health of our children are of at least as much importance and in need of care and the protection of the courts as are their rights in property or under the criminal laws. The law, the court said, cannot to survive be stagnant. It cannot be a dead thing. It must be alive. It must progress as civilization progresses. It must keep abreast of the other arts and sciences in order to justify its existence.

The court concluded, therefore, that where as here the defendant is a physician and knows or should know of the existence of a child en ventre sa mere, he owes a duty to that child. If that duty is disregarded and through his negligence the child is injured while the mother is quick, if it is born viable, an action should lie on behalf of the child for the injuries sustained by it and for any consequential damages resulting therefrom to its parents. The motion to dismiss was therefore disallowed—*Berlin v J C Penney Co, Inc*, 16 A (2d) 28 (Pa, 1940), *Stemmer v Kline*, 17 A (2d) 58 (N J, 1940).

**Malpractice Failure to Cure Not Actionable**—In January 1938, the plaintiff fractured both bones in his right leg between the knee and the ankle and was taken to a clinic operated by the defendant physician. The defendant set the broken bones, placed the plaintiff's leg in a cast and put the plaintiff in bed, where he remained for forty-seven days. In the early part of February, the plaintiff and the defendant entered into a contract whereby the defendant agreed, for the sum of \$750, to furnish the plaintiff all necessary medical attention and hospitalization through March 4, 1938, the contract covering, too, the services already rendered by the defendant. About four weeks after the accident, the first cast was removed. It was found that the plaintiff's leg was bent and his foot twisted and that there was a "sink-hole" where the leg had been broken, but the defendant advised the plaintiff that the "sink-hole" was due to lack of circulation caused by the cast and that it would get all right after the cast had been permanently removed. He then straightened out the foot and applied a second cast. A number of roentgenograms were taken by the defendant from time to time. The plaintiff left the clinic on March 3 but continued to return for treatment, and eventually a third cast was put on. His condition gradually improved to a point where he was able to go about on crutches, but while attending a baseball game some one struck his toe and reinjured his leg.

In July, the plaintiff went to a government hospital in Lexington, Ky, where he stayed for five days. Additional roentgenograms of his leg were there taken and an operation was advised, but the plaintiff refused his consent. He returned home and renewed his visits to the defendant. Some time in January 1939 the plaintiff suggested to the defendant that he would like to have some other surgeon operate on his leg. The defendant therefore sent the plaintiff to a recognized bone specialist and offered to pay any necessary hospital or medical fees, but proper arrangements could not be made. Finally, in April 1939 the plaintiff entered the Veterans' Hospital at Memphis and had a second operation performed. He remained there for fifty-nine days and then moved to the Veterans' Hospital at Johnson City, where he was at the time of the trial. The physicians in the latter institution refused to operate again but attempted to cure a disease condition of the bones in the plaintiff's leg by heat and electric treatments. In a subsequent suit against the defendant for malpractice, the only evidence consisted of the testimony of the plaintiff and his sister. Not one of the roentgenograms which had been taken was introduced in evidence nor were any of the physicians who had seen and treated the plaintiff called as witnesses. At the close of the plaintiff's case the trial court entered judgment for the defendant on a directed verdict, and the plaintiff appealed to the court of appeals of Tennessee, middle section.

In the opinion of the appellate court, the trial court did not err in directing a verdict for the defendant, for there was no evidence of any negligence on the part of the defendant. The utmost effect of the evidence was merely that the leg had failed to recover, that neither the defendant nor any of the other physicians had been able to cure it. A physician is not liable for a mere failure to cure, the court pointed out. He is liable only for failure to use that degree of care and learning which is ordinarily used under similar circumstances by members in good standing in his profession. The evidence afforded no explanation why the leg would not heal or why the bone was diseased. Since this might have been due to causes other than the lack of proper treatment, the court concluded that the doctrine of *res ipsa loquitur* was inapplicable.

The plaintiff also contended that the case should have been submitted to the jury on the question of breach of the contract to furnish medical attention and hospitalization. The court held, however, that the contract, by its terms, extended only through March 4, 1938. The defendant, nevertheless, continued to treat the plaintiff until January 1939 and even offered to pay the fee for a bone specialist to treat the plaintiff's leg. The court held that the contract had not been breached. Judgment for the defendant was accordingly affirmed—*Merryman v Bunch*, 14 S W (2d) 559 (Tenn, 1940).

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Gallbladder Dyspepsia**—Moser and his co-workers analyzed the histories of 49 patients who returned to the clinic because of the persistence of dyspeptic symptoms following cholecystectomy for a calculous gallbladder. A comparison of preoperative and postoperative symptoms with the micropathologic study of the gallbladder showed no correlation between the degree of pathologic change and the expectancy of an operative cure. Among the patients having dyspepsia postoperatively many had severe cholecystitis with stones. This fact suggests that there is little or no relationship between the dyspepsia in disease of the gallbladder and the pathologic degree of cholecystitis. The symptoms of 33 patients were considered to be due to an irritable colon and of the others to food intolerance, diverticulitis of the colon, superficial gastritis, chronic pancreatitis, biliary dyskinesia and chronic inflammatory disease of the pelvis. There was nothing in the histories of the 49 patients to differentiate the dyspepsia from that originating from other sources. Only one observation seemed important. If the dyspepsia was associated only with the acute attack, then relief was likely to follow cholecystectomy. While it is not suggested that the diseased gallbladder with stones should not be removed, the patient should be informed of his chances for obtaining relief from dyspepsia. The true cause of the dyspepsia should be determined before operation and, if possible, measures should be instituted to correct it. The colic due to disease of the gallbladder is generally relieved by cholecystectomy, dyspepsia is not and should not in itself be an indication for cholecystectomy.

**Ileocolostomy with Exclusion for Nonspecific Ileitis**—Colp and his associates report their experience with ileocolostomy with exclusion for the treatment of distal regional ileitis. Ileocolostomy with exclusion is an indirect effective and simpler procedure than one stage ileocolic resection which may be performed in the uncomplicated variety of the disease. Ileocolostomy obviates the necessity for widespread dissection with the possibility of injury to the adjacent and often densely adherent viscera. It avoids extensive raw areas as sites for further adhesions and possibly intestinal obstruction. The possibility of peritonitis from the accidental opening of an encapsulated purulent focus is also reduced. It can be carried out with a negligible mortality by the surgeon who only rarely encounters the disease. Among the authors 40 patients there was no operative death and no serious postoperative complica-

tion. The validity of the objections against ileocolostomy with exclusion, that undesirable mechanical and physiologic conditions might supervene, that healing would fail to occur in the excluded diseased loop and that the continued presence of a primarily diseased segment of ileum would favor the extension of the pathologic process to proximal segments previously uninvolved, are not supported by the results in 40 cases. An overwhelming number of excluded segments of intestine undergo healing. New proximal disease was observed only once, and in that case there was a "skip area" of about 3 feet. In a parallel series of thirteen resections proximal extension was encountered three times. It appears that the deciding factor in the prevention of postoperative proximal disease is not what is done to the primarily diseased segment, but on resection or exclusion at a high enough level. When distal ileitis is complicated by proximal localized or jejunal involvement it may be wiser to resect the proximal lesion, reestablish continuity at that point and exclude the distal segment. Also there are cases of jejuno-ileitis that are not to be treated by either method as sufficient small intestine would not be left to perform adequately the functions of digestion and absorption.

**Prevention of Toxemia of Pregnancy**—Colvin and his colleagues attempted to prevent true toxemia of pregnancy by the administration of thyroid or iodine. Basing their reasoning on the premise that thyroid or iodine limits or prevents a cholesterol-vascular change in the placental vessels and thus lessens the incidence of infarction and toxemia, they have employed this therapy in 273 cases. Iodine proved much more potent than thyroid in preventing true toxemia (as differentiated from vascular disease) of pregnancy. The administration of iodine to patients with vascular disease of pregnancy failed to lower the already low incidence of toxemia among such patients, but when iodine was administered to normal pregnant women the frequency of toxemia was reduced almost 75 per cent. The ophthalmoscope is a most valuable aid in differentiating true toxemia of pregnancy and vascular disease during pregnancy. A low basal metabolic rate is a predisposing factor in true toxemia of pregnancy. Hypercholesteremia induced both by pregnancy and by a lower basal metabolic rate, predisposes to cholesterol vascular change in the placental vessels. This change is the probable antecedent to thrombotic infarction and true toxemia of pregnancy. Lipiodine (Ciba) is a pleasant, well tolerated form of iodine. It does not require an initial or subsequent determination of the basal metabolic rate and, as one tablet is given daily from the end of the third month of pregnancy to full term, an immense reduction in the frequency of true toxemia of pregnancy may be anticipated.

**Treatment of Gonorrhea**—According to Smith and Deakin the coordinated effort of a clinician, a bacteriologist and a medical social worker will aid in the management of gonorrhea in women and improve the therapeutic results in large clinics. A joint male and female clinic aids materially in case control. A comprehensive treatment routine is more effective than haphazard methods. Sulfathiazole is a safe and efficient therapeutic chemical. A single five day 20 Gm course of the drug has resulted in a cure rate of 94.9 per cent. The recently improved results in the treatment of gonorrhea in women at Washington University Clinics are attributed to (1) the use of sulfathiazole, (2) the use of improved methods of culturing the gonococcus, (3) the development of an improved technic of case finding and case holding, (4) the use of an adequate form for statistical analysis and (5) the education of the public about gonorrhea and its cure.

**Ocular and Orbital Wounds of War**—Doherty states that the ingenious devices of war created for the wholesale slaughter of man cause many interesting, weird and freak wounds in all branches of medicine, including ophthalmology. To understand the clinical picture of a fantastic wound of the eye and of the orbit a thorough knowledge of their anatomy must be had. For any injury of the eye or orbit not only the eye and orbit should be carefully examined but the mouth and oral cavity and the bone and skin around it, vision and muscle balance should be determined, intranasal adhesions should be looked for, the exact location of the foreign body should be determined by roentgen study and a complete neurologic study should be included. If roentgenography is not available, probing must be resorted to. This often eliminates a Kronlein operation later to remove fragments of a shell. Many of the so-called red or inflamed eyes treated for inflammation sometimes have harbored foreign material for years, and its presence is finally detected only by a special and careful roentgen study. Five unusual conditions are found in ophthalmologic war surgery: traumatic proliferating choroidoretinitis of Lagrange, spastic entropion (blepharospasm), avulsion of the optic nerve, true or false enophthalmos and a hematic pigmented ring of the disk. The preservation and the tolerance of an eye to foreign material does not depend on the actual microbic invasion but on the chemical decomposition of the foreign substance and on mechanical irritation. The iris and the ciliary body usually react more seriously than does the lens or the vitreous. Copper usually induces a violent inflammation, iron if not encapsulated forms an oxide and causes a discoloration, and the reaction from non-magnetic material is more serious because its extraction causes more trauma and manipulation. The appearance of an injured eye gives no clue as to the absence or presence of a foreign body. Any immediate wound of the orbit or surrounding tissue usually produces swelling, ecchymosis and profuse intraorbital hemorrhage often accompanied by exophthalmos. In the first aid station after asepsis has been carried out the attending surgeon could, by knowing a few important fundamentals, prevent many deformities of the lids and orbit and save many eyes by proper first aid treatment. For extreme exophthalmos a 1:3,000 ointment of mercury bichloride should be instilled in the cul-de-sac, the lids sutured together and an appropriate dressing applied.

The sutures should not be placed directly over the cornea. Restorative work should not be attempted for two to four weeks. This also applies to the removal of or the probing for bullets. No tissue and, above all, no fragments of bone found around the orbital margin should be removed. The attending surgeon's work should consist in replacing the mutilated parts in as good a position as possible and of applying a snug supporting dressing for transportation to the rear. Even if the globe is hopelessly injured the eyeball can be more skilfully enucleated after the ecchymosis and swelling have subsided. There is little danger of sympathetic ophthalmia from a mutilated eyeball allowed to remain in the socket for two weeks. Cartilaginous grafts, adipose grafts and metallic plates have been used successfully for the repair of substance lost from the orbital margin.

**Diseases of Metal Miners**—On the basis of the data obtained from the occupational and medical histories and physical and roentgen examination of 783 metal mine workers in Utah and the determinations of the average concentration of atmospheric dust in the environment, Dreesen and his associates conclude that 1 In Utah mines the prevalence of silicosis (91 per cent) is lower than in certain other areas where lead ores are mined. This is possibly due to differences in the silica content of the ore and the mining operations. 2 While the level of hazard in these mines is not especially acute, lead intoxication occurs. 3 If the atmospheric dust in these metal mines is kept below ten million particles per cubic foot of air, no disabling silicosis should occur and morbidity should decrease. 4 The reduction in concentration can be accomplished by proper use of present control measures. Preemployment and annual medical examinations should enable the physician to detect silicosis, active pulmonary tuberculosis, high blood pressure, nephritis, diabetes, syphilis and heart disease during their incipient stages and to advise the worker on remedial measures.

**Food Poisoning from Smoked Fish**—Kleeman and his associates reporting the occurrence in April 1934 of 32 cases of food poisoning due to smoked fish among residents of Brooklyn and Queens and in 2 visitors from Newark, N J, and in July 1940 of 64 cases of acute gastroenteritis in Brooklyn. Ten of the 98 patients died. No specific food poisoning organism could be isolated on bacteriologic examination of the food. Several samples of fish responsible for the first outbreak. However, several samples had high bacterial counts of *Proteus vulgaris*, which organism, although not considered pathogenic under ordinary circumstances, when found in food may well be responsible for symptoms of food poisoning, and certainly the first outbreak of the organism indicates improper handling of the fish. The source of the fish causing the second outbreak was traced to a health department embargoed approximately 1,000 pounds of smoked fish from this plant found in the retail store. The plant the vats used for washing, soaking and salting is drained directly into a sewer line connected in common with

toilet drain. This sewer pipe emptied into a ditch close to the plant. A sample of the ditch water contained *Salmonella typhi* murium. The persistent efforts of health officials and the cooperation of the more progressive operators have caused food industries to accept the higher standards of sanitation in processing and refrigerating smoked fish. The consumer should be made to realize that smoked whitefish, butterfish and similarly processed fish are perishable foods and require refrigeration at 50 F or below and the utmost care in handling.

#### Voluntary Termination of Artificial Pneumothorax—

Aycock and Keller report 200 cases of artificial pneumothorax voluntarily terminated in order to show that prolonged and indefinite collapse is not applicable to all cases of artificial pneumothorax. The dominant tissue reaction prior to the induction of artificial pneumothorax was exudative in 179, caseous pneumonic in 3 and fibrocavernous in 18. The time range since expansion was completed was from one to sixteen years. The reactivation incidence in the far advanced exudative series indicates that the time element of collapse does not have any bearing on future reactivation after reexpansion is completed. Of 12 cases under collapse for less than eighteen months, the original lesion of 1 reactivated fifty-five months after reexpansion. Of 11 under collapse for three to four years the lesion of 1 reactivated twelve months after reexpansion. Among 13 under collapse for eighteen to twenty-four months the lesions of none showed reactivation. The same was true for 11 cases under collapse for four or more years. Of 36 patients under collapse for two to three years the lesions of 2 reactivated. The incidence of reactivation for these 83 patients was 4.8 per cent. In the moderately advanced exudative cases the absence of any relation between the duration of collapse and reactivation after reexpansion was even more clearly emphasized. The study fails to show any connection between reexpansion and subsequent reactivation. Aside from the inconvenience and expense to the patient of a prolonged and indefinite collapse under artificial pneumothorax, the chief disadvantage is the possible development of serious complications. Prolonged pneumothoraces, with or without effusion sometimes show considerable thickening of the visceral pleura, with a fixation of the collapsed lung which results in the 'unexpandable lung'. Hypertrophy and failure of the right side of the heart and associated mediastinal distortion in such cases assume an increased importance as the end result is grave and deserve further serious study.

#### Pneumothorax Treatment of Pulmonary Tuberculosis

Hurst and Schwartz report the end results in 117 cases in which pneumothorax collapse therapy was employed for a minimum of two years before it was discontinued and the lungs were reexamined. There has been one death, the disease in 79 is apparently cured in 16 it is arrested and in 21 it is active. There were twelve homolateral and seventeen contralateral relapses. The best results were observed in cases with at least four years of pneumothorax. An abrupt cessation of refills and careful watching of the lung as it reexpands appeared preferable to gradual reexpansion of the lung. Early pneumothorax in cases in which the sputum was positive was indicated regardless of the absence of cavity. The best results were observed in

cases of ideal collapse, that is without adhesions to the apex or the costal wall of the lung. The early Jacobaeus operation should be considered when adhesions exist, even though the sputum is negative.

**Minimal Tuberculosis**—Bobrowitz evaluates the methods of treating minimal pulmonary tuberculosis by analyzing the prognosis of this type of lesion in 190 patients with minimal infiltrations discharged from the Municipal Sanatorium, Otisville, N. Y., in 1934 and 1935. One hundred and seventy-six of these patients were again studied in July 1940 and their condition on discharge was compared with their last follow-up examination. Of the patients 124 had unilateral lesions, 44 bilateral lesions, 9 thick pleura and 13 an increase in pulmonary markings, 160 had no complications. At the time of discharge 154 patients had no symptoms, 15 complained of expectoration, 17 of cough and expectoration, 1 had cough and slight dyspnea and chest pain, 1 had digestive disturbances, 1 had lost weight and 1 had fever and convulsions. All but 3 patients had sanatorium observation, bed rest, symptomatic care, gradual increase in physical activities and occupational therapy, in 2 of the 3 pneumothorax was attempted and 1 had pneumothorax. The value of sanatorium care was clearly illustrated. 164 were definitely benefited and were not active at the time of discharge. Even the 10 patients with still active disease were improved, the condition of 11 remained unimproved and that of 5 was unknown. One hundred and seventy-six of the patients received known care after discharge. Comparative roentgenograms were available for 129 and those of 103 were unchanged or improved and those of 26 showed progression or that collapse therapy was needed. If active therapy had been instituted for all the patients, 80 per cent would have had unnecessary collapse therapy. Even after long periods of observation only 15 patients required collapse therapy. It was possible to compare the sputum of 156 patients that of 96 remained negative, of 23 it was converted from positive to negative, of 8 it remained positive, of 29 it turned positive after being negative, and the condition of the sputum of 34 was unknown although in many the tuberculous condition was compatible with a negative sputum. The physical condition of 137 patients on follow-up ranged from excellent or apparently cured to inactive, of 5 it was poor, of 5 it was guarded, of 32 it was unknown and 11 patients had died. The study indicates that routine collapse therapy of minimal pulmonary tuberculosis is not justified as the disease in 75 to 80 per cent resolves or becomes fibrotic or stable with conservative therapy. Collapse therapy should be instituted only when especially indicated.

**Tuberculin in Dermatologic Diagnosis**—Thomas subjected 79 patients with various dermatoses to one hundred and nine parallel tests with purified protein derivative and graded freshly prepared dilutions of a potent old tuberculin. The results confirm those of other investigators and indicate that

the first test dose of 0.00002 mg of purified protein derivative is equivalent to from 0.002 to 0.001 mg of old tuberculin and that the second test dose (two hundred and fifty times the first) is equivalent to approximately 1 mg of old tuberculin. No positive reactions were obtained with the purified protein derivative in persons in whom they were not also elicited with old tuberculin and vice versa. Purified protein derivative is therefore specific in detecting sensitized persons.

**Radium Pads for Cutaneous Disease**—Isaak reports excellent results in the treatment of 85 patients with various cutaneous diseases with radon ointment or radium pads. Radon, the first product of decay of radium, can be separated from its mother substance by suction into a vacuum, and if melted petrolatum is sucked into the same vacuum and thoroughly shaken a uniform radon ointment is created. The ointment is placed in small collapsible tubes. A radium pad has a body or carrier of linen or of a fine meshed webbing of bronze or silver on which radium salt is spread uniformly in as fine a layer as possible with a good lacquer. A radium pad looks like a piece of oiled silk, is flexible and can be molded to the contour of the body. The pad keeps its radioactivity practically all the time and is therefore always ready for use, while the ointment loses half of its intensity within about four days. The radon ointment and radium pad treatment was successful for cases of chronic lichen simplex, chronic lichenified eczema, lichen planus, hypertrophic lichen, marginal eczema and vulval kraurosis with leukoplakia. The results were less satisfactory in cases of psoriasis. The treatment seemed to have an excellent effect on arthropathic psoriasis. The improvement in 1 of 2 cases of syccosis vulgaris was satisfactory. The condition in more than half of the patients with anal, vulval or scrotal pruritus healed or improved, but the results were not entirely successful and could well be improved. The use of the radium pad was preferred because of its flexibility, ease of application, uniform radiation output, better results obtained with it and the shortened time of treatment.

**Shock Syndrome**—Stead and Ebert studied a group of patients with known heart disease to evaluate the role of the heart, the peripheral vascular system and the blood volume in producing the shock syndrome seen in certain patients with congestive cardiac failure and in some with acute myocardial infarction. These patients present signs of a decreased peripheral blood flow with a diminished or an absent radial pulse, cold extremities, narrowed pulse pressure and a relatively well maintained diastolic pressure. The patients with congestive failure had an elevated systemic venous pressure but in those with acute myocardial infarction but no congestive failure this pressure was normal but extreme pulmonary congestion and edema was exhibited. There was evidence of slight hemoconcentration in patients with acute myocardial infarction, probably owing to loss of fluid into the lungs. Because of the simultaneous presence of diminished peripheral blood flow and congestion of the pulmonary or of the systemic venous bed, it is thought

that the clinical picture of shock is produced by heart failure rather than by an inadequate venous return due to a decrease in blood volume or to peripheral pooling of blood. Peripheral circulatory failure and shock should not be applied to the signs incident to a decreased cardiac output due to heart failure but should be restricted to conditions in which the cardiac output is diminished because of an inadequate venous return.

**Chickenpox in Adults**—During the last twelve months 4 persons more than 26 years of age with chickenpox were encountered at the Colorado General Hospital. Waring and his associates cite 2 cases in which the chickenpox was complicated by pneumonia and in 1 by fatal encephalitis and nephritis. Both patients were healthy, robust men, who had contracted the disease from children in whom the course was mild. The main anatomic features in the 2 cases were (1) severe and generalized chickenpox, (2) severe, confluent, mononuclear and proliferative lobar pneumonia, (3) only in the fatal case an acute, toxic, moderate and diffuse encephalitis with purpura of the white matter and (4) acute, toxic and moderate nephrosis. The authors draw attention to the chickenpox virus as a possible cause for the mononuclear and proliferative pneumonia in man. Neurologic complications of varicella are not rare. In the fatal case all types of lesions were present, but some of them were only slight or moderate in intensity. The chief macroscopic and microscopic characteristic was the vascular disturbance, which pointed to a pronounced vasotoxic action of the virus. Petechial and hemorrhages dominated the picture. This is apparently the first case of cerebral involvement following chickenpox in an adult with necropsy to be reported. Only further necropsy reports will permit a more definite classification of encephalitis varicellosa. Special attention should be given to perivascular (perivenous) demyelination, with or without lesions of the axis cylinders, described in the literature and observed to a certain extent in the present fatal case. The relation of chickenpox encephalopathy to perivenous encephalitis is not incompatible with a relation to multiple sclerosis. Future study of the demyelination in chickenpox encephalitis may enhance the knowledge of the etiology and the pathogenesis of multiple sclerosis. Their microscopic examination of the renal sections lead the authors to believe that the likely cause for the renal changes was the virus of chickenpox.

**Addison's Disease**—Willson and his co-workers employed the sodium chloride excretion test (after fifty-two hours of restriction) of Cutler, Power and Wilder (*The Journal*, July 9, 1938, p. 117) in the diagnosis of Addison's disease. 19 cases. The diagnosis in 11 had been made on clinical grounds and the test was used to obtain confirmatory evidence of the efficacy of the procedure, in 5 the test was a necessary adjunct in establishing the proper diagnosis, and in 3 the test was performed during treatment with desoxycorticosterone acetate. In addition, the test was employed in 44 cases of a variety of conditions, including many of "functional" asthma. Of the 16 patients with Addison's disease who were not receiving desoxycorticosterone, 10 were unable to withstand the fifty-two hours of salt restriction. The 10 patients had sufficiently severe symptoms of crisis to permit the diagnosis of Addison's disease on clinical grounds. The concentration of chloride in the final four hour specimen of urine of 5 of the 6 patients in whom the test was complete was more than 225 mg per hundred cubic centimeters, while that of sodium was more than 165 mg. Examination of the composition of the plasma in the sixth patient revealed evidence of adrenal cortical insufficiency. The 3 patients with the disease who were receiving desoxycorticosterone responded like subjects without the disease, that is, with a great increase in the excretion of sodium chloride. The great value of the salt restriction test has been in excluding the possibility of Addison's disease. Of the 44 patients examined, 21 were classed as suffering from nervous exhaustion, infectious exhaustion, vagotonia, neurocirculatory asthenia and anxiety, 11 had certain manifestations which were some of those in Addison's disease and 12 had various functional and organic disorders. The 44 patients with 1 exception responded with typically low concentrations of sodium chloride in the final four hour specimen of urine. The only exception the concentration of sodium and chloride in the

in the plasma the patient failed to react unfavorably to the salt restriction and thus aided in excluding the diagnosis of Addison's disease. The test subjects the patient with Addison's disease to some danger and the clinician should be prepared to recognize and to treat acute adrenal cortical insufficiency, should it occur.

**Surgical Treatment of Cancer of Skin**—Fleming reports 5 cases of advanced or extensive cancer of the skin, 2 of the patients have died and 3 are living, respectively two, three and four years after radical surgical removal with no evidence of disease. Prophylaxis in this type of cancer is possible by proper treatment of burns, early cutaneous grafting with skin of adequate thickness to prevent subsequent scarring or contracture. Granulomas and other cutaneous chronic irritations should be dealt with similarly if conservative measures fail to produce cure.

**Quinine as Prophylactic in Influenza**—Barge believes that, since quinine causes a leukocytosis and increases the body defenses during the initial stage of influenza, it might be given as a prophylactic. Evidence indicates that the incidence of influenza is much lower among persons taking quinine than among those not using the drug. As physicians studying defense with regard to national health, it is well to impress on the younger men the seriousness of the disease and the importance of quinine as a possible prophylactic. In Florida, to which people from all parts of the country come to hotels, tourist camps, army camps and aviation fields, an epidemic is likely. Many authorities have stated that influenza is practically unknown among people who take quinine.

**Etiology of Acute Infectious Gingivostomatitis**—Black presents clinical and experimental evidence which demonstrates that herpes simplex virus is the primary etiologic agent of acute infectious gingivostomatitis, which condition, he suggests, should be known as acute herpetic gingivostomatitis. The course of the experimental lesion in the inoculated rabbit's eye is typical of herpetic keratoconjunctivitis produced by known strains of herpes simplex virus. The infection is easily transferred to other rabbits. The lesion in the rabbit's eye contains intranuclear acidophilic inclusion bodies indistinguishable from

those produced by known strains of herpes simplex virus. After the infected animals recover they are immune to further virulent inoculations. The agent, carried in serial inoculations of rabbits and mice for months, produces uniformly the typical clinical picture of fatal herpetic encephalitis when injected intracerebrally into rabbits or mice. The presence of the herpes simplex virus in the lesions of acute infectious gingivostomatitis is neither incidental nor accidental but etiologic. The virus is not commonly present in the normal mouth or in mouths with other types of inflammation whereas it is found on a single examination in approximately 90 per cent of the mouths in which there is acute infectious gingivostomatitis. Humoral immunity is present after the disease has run its course, but it is not commonly present during the early stages of the disease. Ten, or more than 40 per cent, of 23 patients were known to have been intimately exposed to a source of herpes virus, whereas only 8 per cent of patients with other types of oral inflammation gave such a history. A typical attack of acute herpetic gingivostomatitis followed inoculation of a volunteer's mouth with the fluid from the vesicles of a herpes simplex lesion.

**Diphtheria and Tetanus Alum Toxoid**—Since 1937 Deamer and his associates have given combined diphtheria and tetanus alum toxoid to 600 infants less than a year old. At first three injections of 1 cc of toxoid were given at intervals of one month. Recently the interval was lengthened to two months. Two months or more after the last injection a Schick test was made and blood was obtained by venipuncture from 242 infants to determine the tetanus antitoxin content by guinea pig assay. The variation in tetanus antitoxin response was considerable, but the blood of all of them contained more than 0.01 unit and of some as much as 10 units of antitoxin per cubic centimeter of serum. Schick tests were negative in 96 per cent, and the infants tolerated the antigen well. A study of their response to a late 'recall' injection of tetanus toxoid is in progress.

- Ocular Tuberculosis P C Kronteld Chicago—p 66

**Upper Respiratory Infections**—Victor states that individual resistance determines the effect of preventive and immunization measures against the common cold and related infections of the upper part of the respiratory tract. The factors that influence the individual resistance are dietary deficiencies, fatigue, general systemic diseases, anatomic variations, contacts, exposure, climatic conditions, environment, social status, epidemic prevalence, occupation and geographic locations. Assuming that the symptoms, severity, complications and duration of a cold may be prevented or lessened by decreasing the virulence and number of organisms present, the advantage of immunization of 500 employees of an industrial plant with oral and with subcutaneous vaccine over four years was evaluated. The first year (September 1935-March 1936) with no immunization measures the 500 subjects had an average of three and six-tenths colds of an average duration of five and seven-tenths days and there were 45 cases of pneumonia per hundred patients. The corresponding figures for the second year for the 250 employees given six injections of 0.25 to 1 cc of vaccine subcutaneously at intervals of three days were two and six-tenths, four and six-tenths and 3, and for the 250 untreated employees the figures were three and four-tenths, five and three-tenths and 4.5. The third year 166 subjects were not treated 167 were given six subcutaneous injections of vaccine and 167 were given one capsule of oral vaccine for seven days and then one capsule two times a week until March. The figures for the colds, their duration and the number of cases of pneumonia for the three groups were three and five-tenths, five and six-tenths and 6.01, two and three-tenths, four and three-tenths and 2.25, and two and eight-tenths, four and six-tenths and 4.51. The fourth year

the 500 employees were divided into five groups of 100 subjects and each group was given varying amounts of subcutaneous or oral vaccine for different lengths of time. The group given 0.25 to 1 cc of vaccine subcutaneously every three days for six injections and then 1 cc every month and also one capsule of oral vaccine for seven days followed by one capsule two times a week had the least number of colds (one and eight-tenths) of the shortest duration (two and eight-tenths days) and among them there was only 1 case of pneumonia.

\*Chigger and Jigger Bites J E Weigel—p 189

**Chigger and Jigger Bites**—Weigel states that, since the irritation and discomfort from bites of chiggers and jiggers have an unfavorable effect on the morale and physical well being of troops, medical officers should have knowledge of their prevention and treatment, especially the medical officer in a warm region where the two mites are prevalent. A check made on 200 soldiers who spent ten days in the field during July 1941 revealed that 78 per cent had three or more chigger bites on their return to the garrison. The fierce, maddening itch is not due to the bite but to the liquefaction of epidermal tissue by a digestive secretion that the larva of the chigger injects into the wound. Prevention is preferred to treatment, and powdered sulfur is the best repellent. Four parts of a vanishing cream known as "Hazeline Snow" mixed with one part of powdered sulfur and applied to the skin leaves an almost invisible film of sulfur. When it was applied before going into the fields and reapplied after a soapy shower on return to camp none of the treated men had chigger bites, while unprotected men had numerous lesions. If the cream was applied to bites early, it ameliorated the pruritus and hastened healing. To remove the larvae present on the skin, a half hour of bathing with plenty of soapy water and then, after drying, a light application of the cream followed by a complete change of clothing is recommended. To relieve the intense itching and irritation the lesions should be sponged with 70 per cent alcohol several times a day, and a boric acid ointment containing 0.65 Gm of phenol and 0.32 Gm of menthol to the ounce should be spread on lightly followed by the dusting on of borated talcum powder. The bites of the sand flea or jigger produce similar lesions. Their prevention is based on the elimination of breeding and hiding places, clearing up of rubbish, admitting sunlight to dark places and filling up cracks and crevices in buildings. The most useful repellents are camphor and sulfur. A solution of camphor, menthol and phenol painted on the skin is of value. A small amount of the sulfur cream recommended for preventing and treating chigger bites destroys the insects. Sulfur fumigation can be used to destroy the insects hiding in barracks or buildings. If the sulfur cream is used constantly, the possibilities of dermatitis from sulfur irritation and toxic effects must be considered.

**Diphtheria Toxoid for Leprosy**—Faget and Johnston point out that because of the favorable report of Collier on the treatment of leprosy with diphtheria toxoid 1 cc of diphtheria toxoid was given every month for up to twenty months to 47 patients at the United States Marine Hospital at Carroll, La. The study was controlled by giving 35 patients similar doses of the broth from which the diphtheria toxoid is produced. The results in the control group were better than those in the group given toxoid. There is no indication that the treatment has a favorable effect on leprosy.

**Influence of Laxatives on Gastrointestinal Motility**—Bruck and Fruchter studied the gastrointestinal motility of apparently healthy young volunteers following the administration of a single dose of commonly used laxatives: cascara, 1 powder, magnesium citrate, magnesium sulfate or castor oil. For a control the gastrointestinal motility of each subject

studied a week or ten days preceding the study with laxatives. Roentgenograms were made immediately and one hour, three, four, six, eight, twenty-four and forty-eight hours after a barium sulfate meal. Fluidextract of cascara sagrada and compound powder of senna did not alter the control gastric evacuating time. The magnesium salts—citrate and sulfate—and castor oil delayed gastric motility. Each laxative caused an initial irritability of one to three hours of the proximal jejunum. With magnesium sulfate there was a definite delay in the passage of the meal through the small intestine. The other laxatives moderately increased the motility of the small intestine. Fluidextract of cascara sagrada slightly increased the emptying time of the colon. Compound powder of senna and castor oil produced the most satisfactory and complete emptying of the colon. There was more retention at forty-eight hours after the taking of either of the magnesium salts, in spite of numerous defecations, than the control. Castor oil and compound powder of senna appear to be the best laxatives for colonic cleansing in preparing the patient for roentgen examination.

Hemorrhages into Anterior Chamber H L Hilgartner Jr Austin and A Pfirsch San Antonio—p 681

**The Blood in Acute Appendicitis**—Dutton plotted the total leukocyte counts and neutrophils of 70 patients before they were operated on for acute appendicitis of 17 for subacute appendicitis and of 25 for chronic appendicitis. Postoperatively the pathologic diagnosis was acute diffuse appendicitis in 31, acute catarrhal appendicitis in 36, chronic appendicitis in 20, subacute appendicitis in 6 and fibrosed appendix in 24. All but three of the leukocyte counts were above 12,000 leukocytes per cubic millimeter and a percentage of more than 80 for the neutrophils. It seemed fairly clear that if the blood count is above 12,000 and the polymorphonuclear percentage above 80, acute diffuse suppuration of the appendix should be expected when the rule of immediate operation is in full force. If definite clinical indications of appendicitis are present but the blood count falls below the aforementioned figures the chances are that the appendix will be in the catarrhal stage. A catarrhal subacutely inflamed chronically inflamed or fibrosed appendix cannot be determined by blood counts. Little diagnostic aid is to be

obtained by considering the percentage of immature neutrophils in appendicitis, as an essentially similar variation is present in all cases. If eosinophils are present there is little likelihood that diffuse suppuration will be present.

**Body Weight in Spontaneous Myxedema**—Plummer presents data on 200 cases of spontaneous myxedema which emphasize that overweight need not necessarily accompany the disease. The data consist largely of a correlation between the theoretically normal weight and the individual variable. Of the 200 patients 25 per cent were men and 75 per cent were women. The average age of the men was 47.4 years and of the women 48.4 years. The weight of 123 patients was from 1 to 50 or more pounds (0.4 to 22.7 Kg) above the theoretically normal weight and of 77 it was normal (in 3 only) or 30 or more pounds (13.6 Kg) below normal. The average basal metabolic rate of the patients in whom the theoretical weight was greater than normal was  $-31.4$  and of those whose weight was normal or less than normal it was  $-34.6$ . For the entire group the average actual weight was  $10\frac{1}{10}$  pounds (4.6 Kg) more than the theoretically normal weight at the beginning of treatment. Contrary to what might be expected, the patients having the highest basal metabolic rate, that is those with the least severe myxedema, were, on the average, the most overweight,  $21\frac{3}{10}$  pounds (9.7 Kg). The decrease in overweight was progressive in the direction of the lowest basal metabolic rate. The data warrant the conclusion that when the disease is well established, or at least severe there is an actual loss of body tissue which may not be apparent because of its being replaced by edema. Furthermore, the loss of body tissue becomes progressively greater as the disease becomes more severe. When the edema in spontaneous myxedema has been eliminated by the administration of thyroid, the patient may still be undernourished because of the previous cachexia. Later, if the basal metabolic rate is maintained within normal limits, the patient tends to gain weight by acquiring normal body tissue.

**Sulfathiazole Locally for Peritonitis**—Pearl and Rickles state that the intraperitoneal introduction of sulfathiazole in sufficient concentration is effective in controlling and combating peritonitis produced in the rat by inoculating a pure culture of hemolytic *Escherichia coli*. Simultaneous introduction of a suspension of sulfathiazole with a dose of *Esch coli* culture which alone produced a fatal peritonitis in rats completely protected the rats from any detectable peritoneal or systemic reaction. When a suspension of sulfathiazole was introduced ten hours after the peritoneal cavity was infected, all but 1 animal survived. Definite positive signs of an active spreading peritonitis were present in all before the drug was administered, and the infection left no residua in the recovered animals. Sulfathiazole apparently exerted no harmful effects on the peritoneal cavity. Local application of sulfathiazole at the site of infection causes an immediate high concentration of the drug at the place where it is needed. This inhibits the growth of the colon bacillus, and thus the phagocytes can remove the contaminating material. Study of the blood levels of sulfathiazole in a number of rats suggests that the absorption of the drug from an infected peritoneum is more rapid than from a normal peritoneum and that a blood level is maintained that could combat any bacteremia present in active peritonitis.

**Periodic Somnolence and Morbid Hunger**—Critchley and Hoffman believe that the syndrome of periodic somnolence and morbid hunger described by Kleine and by Levin is a definite entity. Two cases are reported. Levin believes that there is a periodic excess of inhibition exerted by the highest cerebral centers, including those controlling gastrointestinal motility. From a study of their 2 cases the authors can form no definite conclusion as to the morbid anatomy and physiology of the syndrome. Despite the abnormal electroencephalographic changes in 1, the suggestion of a frontal lobe dysfunction is by no means convincing and they are far more tempted to suggest a pathophysiologic process within or near the hypothalamus. The changes were similar to those observed in epilepsy or in cases of epileptic predisposition in which fits never occurred. This probably indicates the existence of a cerebral dysrhythmia. Blood sugar and electroencephalographic studies during attacks might furnish more helpful data. Dextrose and insulin tolerance tests in 1 case indicated that hypoglycemia was not responsible. Apart from the drowsiness and hunger there were no other symptoms suggestive of hypoglycemia.

**Casualty Compression of Abdomen at Sea**—Breden and his associates describe the visceral injury that is caused by compression or suction waves set up by the detonation of high explosives on land or at sea. Organisms permeating a contused colon were the cause of pelvic and subphrenic abscess which 2 patients had who recovered after drainage. There were 7 patients with severe melena but without serious complications who recovered, but 1 patient with lacerations of the ileum, peritonitis and compression injuries of the lungs died after a laparotomy and suture of the perforation. In addition to the abdominal injuries, blast effects in the lung were seen at necropsy of the patient who died. The patients who survived did not show symptoms or signs of severe blast injury to the lung. The immediate symptoms (vomiting with blood, diarrhea with melena and testicular pain presented by 4 patients) after sudden compression were not severe. The testicular pain was probably due to a direct compression effect. No patient had external bruising. None of the patients were seen in the first twenty-four hours. The results justify conservative management. Neither of the 2 patients with abscess showed positive signs demanding immediate laparotomy. Microscopic study of the lungs and small intestine of the patient who died disclosed edematous patches with many carbon particles and some basophilic debris. Many macrophages, attributed to the inhalation of sea water and fuel oil, were present. Sections of the ileum showed the hemorrhages to be most severe in the submucous and subperitoneal layers of the intestine. The hemorrhages in the intestine were more diffuse than was suggested macroscopically.

**Outbreak of Paratyphoid B in Bristol**—Between Aug. 18 and Oct. 30, 1941, 268 cases suggestive of paratyphoid B infection were reported in Bristol. Laboratory evidence of the infection, Davies and his co-workers say, was present in 244 and clinical paratyphoid in 203; there were 41 intestinal carriers. Investigation of the source of infection disclosed a common confection prepared by one firm. Investigation of the firm's premises and staff narrowed down to a girl employee who had had a vague history of headaches and malaise and had ceased to work on August 2. She was visited and persuaded to have her blood and feces examined. *Salmonella paratyphi B* was isolated from the feces. Of 167 patients with the primary disease 102 (61 per cent) had consumed artificial cream from the confectionery. Opportunities for infection of this cream by the girl employee were present in each instance. Of the 41 intestinal carriers, 19 had consumed artificial cream from the firm, 9 were members of families in which a known case had occurred, 6 belonged to a family known to have consumed infected cream and 13 were untraced. Of the 244 patients with established infection 149 (61 per cent) were known to have either consumed food material which was known to be infected or were in intimate contact with a person known to have paratyphoid. Of the remaining 95 with untraced infections the onset of the illness of 65 began during the primary wave of the epidemic with similar dates of onset and a similar peak. A number of strains of the paratyphoid organism isolated from cases arising during and after the primary wave reveals that they are all of the same phage type, type I, which at present is common throughout the country. The best method of controlling epidemics of paratyphoid B is by examining the feces, Widal tests will miss many cases in the early stage. Bacteriologic study must also be made of the feces of all contacts and of people engaged in handling food. The management of all food factories must be impressed with the importance of strict cleanliness among the food handlers. Adequate washing and facilities for clean linen must be provided.

**Bacteriology of Epidemic Paratyphoid**—Holt and his associates believe that the value of fecal cultures in the diagnosis of paratyphoid is illustrated by the fact that of 466 cases of paratyphoid B that recently occurred in and around Liverpool 96 per cent were confirmed by this method. The method was equally diagnostic at all stages of the infection, including the first week. Positive cultures were obtained at the first attempt from 402 of 439 cases (92 per cent), at the second from 32 and at the third attempt from 5. Fecal infection was particularly slow to clear up in women more than 20 years of age. Of 7 women more than 40, 9 continued to excrete paratyphoid bacteria in the feces for more than sixteen weeks. The ultimate origin of the epidemic is still uncertain, but its great extent appears to have been due to contamination of synthetic cream. This contamination was regarded as an accident in the history of 10 or more persons who became infected in the early days of the epidemic and whose occupation permitted them to infect many more other persons in the same place of employment, who may have contributed their quota to the final result. The employees who were infected early when detected at home with conditions labeled gastritis but which were actually paratyphoid, the other infected employees were detected while still at work. These facts emphasize the importance of bacteriologic examination of even mild intestinal disturbances and too that the hygiene of large bakeries requires more supervision.

\*Pathologic Aspects of Cerebrospinal Fluid in Poliomyelitis (Meningitic and Paralytic Stages) P Lotscher—p 578

Ferment Chemistry of Human Spermiatic Fluid C A Joel—p 595

Study of Parathyrogenic and Idiopathic Forms of Tetany T Vitti—p 601

**Cerebrospinal Fluid in Poliomyelitis**—Lotscher is concerned with the cerebrospinal fluid of the second and third stages of poliomyelitis after the invasion of the central nervous system by the virus. The first stage is characterized clinically by the absence of neurologic symptoms and a normal cerebrospinal fluid. Many patients are cured during the first stage. The majority of these purely "abortive cases" are not diagnosed. The author is concerned with 101 patients hospitalized during the second and third stages of poliomyelitis and subjected to one or several spinal punctures. The fluid pressure was normal in 44 per cent (70 to 150 mm of water), in 43 per cent it was moderately increased (150 to 200 mm) and in 13 per cent it was greatly increased (over 200 mm). There was no complete parallelism between pressure and cell count though the high pressures were usually accompanied by rather high cell counts. The Queckenstedt phenomenon was always positive. The cerebrospinal fluid was water clear in the majority of cases but when the cell count was high a slight turbidity was visible against a dark background. Obvious spider web formation was observed in 2 cases xanthochromia in 1. The cell count was increased in about 98 per cent. Cell counts of more than 1000 were observed chiefly in the meningitic types. In the paralytic types the polyplegic patients usually had higher counts than did the monoplegic ones but there was no parallelism between the severity of the disease and the cell count. There were a number of fatalities among patients with rather low cell counts. Following invasion of the virus into the central nervous system the cell count increases rapidly to maximal values, so that the first puncture usually reveals the severest pleocytosis. The polymorphonuclear cells usually predominate over the mononuclears in the first puncture. This predominance persists generally beyond the rapid decrease in the cell count during the first week and is replaced by a mononucleosis only after from two to four weeks. The Pandy reaction was positive in 71 cases, Nonne's reaction in 33. The first puncture disclosed an increase in the total protein content in only 42 per cent of the cases; subsequent punctures increased this figure to 50 per cent. The incipient cytoalbumin dissociation gradually changes into an albuminocytologic one. The increase in the total protein content is of no prognostic significance. The colloidal gold reaction is of limited prognostic significance. The sugar content of the cerebrospinal fluid was normal in 79 per cent of the cases. The supposed unfavorable prognosis of increased sugar content could be corroborated in only two of the nine fatalities. The rarity of decreased sugar values is helpful in the differentiation from other forms of meningitis particularly tuberculous meningitis. There is no one aspect of the cerebrospinal fluid that is characteristic of poliomyelitis. However positive findings in the cerebrospinal fluid, together with the history and clinical signs, permit the diagnosis of poliomyelitis during the meningitic stage. In paralytic forms positive observations in the cerebrospinal fluid are of differential diagnostic significance.

Sulfanilamide Through Arteries J Saldanha Faria—p 473

Electroanalgesia in Tuberculous Painful Dysphagia E C F Mondadori and F Laria Pereira—p 501

**Sulfanilamide Through Arteries**—Saldanha Faria advocates the arterial route for administration of sulfanilamide in local infection of extremities. The injection is made into the main artery of the limb into the radial in the case of infection of the hand and forearm into the subclavian above the upper border of the clavicle in infections of the arm and into the femoral artery at the base of Scarpa's triangle in infections of the legs. The injection is made slowly with a 6 cm needle of the type used for lumbar puncture. The injection is made

in the direction of the blood stream. After the injection the needle is quickly withdrawn and the point of injection is compressed for a few minutes. The injection is harmless. It produces a local analgesic effect and is not accompanied by unpleasant general reactions or vasomotor phenomena. Indications for intra-arterial injections of sulfanilamide are local infections of the extremities, erysipelas, acute and subacute lymphangitis, abscess, infected trauma, chronic ulcer, osteomyelitis, wet gangrene, compound fractures and acute and subacute arteritis. The earlier the administration of intra-arterial injections of sulfanilamide the more rapid and better the effect.

**Electroanalgesia in Tuberculous Painful Dysphagia**—Mondadori and Faria Pereira direct attention to Gran's method of "electroanesthesia (iodine ionization) of the larynx" and the value of the procedure in the therapy of acute painful swelling in tuberculous laryngitis. The metallic electrodes of steel and tin, respectively, are bent to the form of the throat and back of the neck. The concave part of each electrode is filled with a thick layer of cotton. The anterior electrode is soaked in a 2 per cent potassium iodide solution and the posterior one in water. The electrodes are firmly applied to the throat and back of the neck by means of an elastic bandage. A galvanic current of 12 milliamperes is passed through the electrodes for thirty minutes. Pain stops completely within the first fifteen minutes of the treatment. It reappears within or after twenty-four hours. In either case the treatment is repeated only when pain recurs. The intervals of recurrence of pain after the first twenty-four hours rapidly increase from several days to several weeks. All patients can resume normal feeding immediately after the first treatment. The treatment controls pain permanently without any effect on the course of the tuberculous laryngeal lesions. Edema of the larynx is the only contraindication. Administration of local and inhalation anesthesia and local trauma of any degree are prohibited, as they nullify the effects of electroanalgesia. The treatment is painless, harmless and simple. It gives good results in all cases regardless of the stage and extension of the involvement.

\*Therapeutic Abortion and Malignant Endocarditis Lenta I Taddeo—p 16

**Therapeutic Abortion and Malignant Endocarditis Lenta**—Taddeo stresses the inadvisability of inducing abortion in women with heart disease, especially in the presence of a history of rheumatic fever. Abortion may be the cause of Streptococcus viridans infection and consequent development of a malignant endocarditis lenta due to the passage of bacteria from the operative wound to the blood and the predisposed heart valves. Pregnancy in women with heart disease can be carried to full term if the patients are under constant medical care. Abortion is indicated only in exceptionally rare cases of grave heart disease in which cardiac insufficiency appears in the first three months of pregnancy and cannot be controlled. The author prefers high cesarean section with sterilization of the patient to abortion. A case of malignant endocarditis lenta after abortion in a woman with heart disease of rheumatic origin is reported.

\*Tuberculin Tests and Roentgen Examinations of Thorax of 1462 Young Men A Alemaný Selfa and A Gomez Lopez—p 559

**Tuberculin Tests and Roentgenograms**—Alemaný Selfa and Gomez Lopez performed tuberculin tests and roentgen studies on 1462 apparently normal young men between the ages of 20 and 27. The Pirquet tuberculin skin reaction was positive in 1349 men. The Mantoux intradermal test was performed on the group of 113 men who gave a negative or doubtful tuberculin skin reaction to a dose of 0.1 cc of 1:1000, 1:100 and 1:10 tuberculin dilutions. Thirty-five men gave a positive reaction to the 1:1000 tuberculin dilution, 18 to the 1:100 and 13 to the 1:10 tuberculin dilution. Negative reactions were observed in 47. Roentgenograms of the chest showed

tuberculous lesions in 11 cases. The disease was in a stage of evolution in 8 cases. There were residual tuberculous pleural lesions in 100 and residual tuberculous pulmonary lesions in 133. Allergy was more frequent in the city dwellers than in those who lived in the country, but the difference was small.

Radiologic Examination of Gastric and Duodenal Ulcers M Arias Schreiber —p 577

**Anxiety Neurosis Treated by Metrazol**—Sal y Rosas employed metrazol in the treatment of neuroses. He found that the provoked attacks exert a favorable influence particularly on the symptoms of anxiety. Metrazol treatment was found to be extraordinarily efficient in anxiety neuroses, 8 of the 9 patients treated with it having had a more or less lasting remission. The 1 patient who did not respond proved subsequently more amenable to medicinal treatment and to psychotherapy. Not a single case of aggravation was observed. In anxiety, as in other forms of neurosis, favorable results were obtained with injections that did not produce a convulsive effect. The neuroses of shortest duration reacted most favorably to metrazol treatment.

\*Determination of Sulfanilamide in Bone Marrow Considerations on Origin of Sulfanilamide Neutropenia from Changes of Hemogram and Myelogram L Ayres and D Pedrosa —p 187

**Sulfanilamide in Bone Marrow**—Ayres and Pedrosa studied hemograms and sternal myelograms in 3 cases in the course of sulfanilamide therapy and after and made quantitative determinations of the sulfanilamide in the venous blood and in the sternal marrow. They found that sulfanilamide is stored in the bone marrow. The amount in the bone marrow is twice that in the venous blood for more than two or three weeks after discontinuation of the treatment. The time of "delay" for therapeutic action of sulfanilamide, when small doses of the drug are administered, is time necessary for the accumulation of the drug in the bone marrow. Sulfanilamide impregnates the protoplasm of the neutrophilic leukocytes, which are the carriers of sulfanilamide in the blood. Sulfanilamide impregnation of the bone marrow tissue results in a greatly retarded maturation of erythroblasts and myelocytes with consequent development of peripheral erythropenia and neutropenia. The bone marrow is a good reservoir for sulfanilamide as well as tissue capable of conveying the drug to the blood by the neutrophil leukocytes. This suggests the advisability of injecting sulfanilamide into the sternal bone marrow to obtain rapid results.

\*Consideration of Nutritional Value of Oysters C Blanco Soler —p 360

**Immunotransfusion in Chronic Osteomyelitis**—According to Gomez-Duran, surgical treatment does not always effect a cure in fistulous osteomyelitis. Various considerations indicate immunotransfusion as a complementary treatment. Chronic osteomyelitis causes grave disturbances in the serum proteins, and this makes the transfusion of plasma proteins advisable, the use of vaccine and chemotherapy is likewise helpful in osteomyelitis. Immunotransfusion preceded by vaccination and sulfanilamide treatment of the donor combines these different

factors. The author considers immunotransfusion advisable as a complementary treatment after a surgical intervention and as the only treatment in cases of diffuse infection without sequestrum formation in which operation is not indicated. He employs it in practically all cases of osteomyelitis complicating fractures. The immunotransfusion is given within a week after the surgical intervention and is followed by the occlusive treatment of Orr.

**Nutritional Value of Oysters**—Blanco Soler states that the popular belief that oysters should not be eaten during the months without an r (May, June, July and August) is unfounded, except that their nutritive value is slightly less at this time. Oysters are rich in protein and in amino acids and compare favorably with meat and eggs. They also contain readily assimilable mineral salts, such as copper, manganese, calcium, iron and iodine. Green oysters contain lecithin, which provides phosphorus in an advantageous form. Carbohydrates are present as glycogen. Vitamins A and D are present in abundant quantities and B, C and G in appreciable amounts. The digestibility of raw oysters compares with that of raw eggs or milk, cooked oysters remain in the stomach somewhat longer. Because of the high iron, manganese and copper content, oysters have long been recommended for anemia. That eating oysters results in regeneration of the blood has been demonstrated in experiments on rats. In pernicious anemia, oysters can be estimated next to liver. The author recommends the combination of liver therapy with the eating of oysters, the more so since they stimulate the appetite when eaten before a meal, furthermore, they increase the production of the gastric and pancreatic juices. Oysters influence the regeneration of hemoglobin more than the augmentation of the erythrocyte count. In anemias and in hepatic disorders accompanying them the glycogen content of the mollusks and their richness in diastases should not be forgotten. The concurrence of vitamins A and D and of iodine makes them recommendable for use in rickets. Because of their high vitamin content oysters have been recommended also in the treatment of scurvy and of pulmonary tuberculosis. The vitamin C content of oysters is probably explained by the presence of this vitamin in the aquatic vegetable matter which they consume.

Surgical Interventions in Gunshot Wounds of Pelvic Bones C Reimer —p 33

\*Treatment of Infected Wounds with Potassium Permanganate Boric Acid Solution and Powder B von Mező —p 43

\*Potassium Permanganate Boric Acid Powder in Wound Treatment I Györfy —p 45

Shearing Off Fractures of Tuber Calcanei F Jimeno Vidal —p 46

\*Esophageal Stricture After Diphtheria Continuous Dilatation F Weigand —p 51

\*Synovial and Anthomatous Tumors H C a Wengen —p 55

**Treatment of Infected Wounds with Potassium Permanganate-Boric Acid Solution and Powder**—Von Mező demonstrated that combination of ineffective and weakly acting solutions may increase the bactericidal action without injury to the tissues. Finely powdered boric acid and potassium permanganate, mixed in the ratio of 100 Gm of boric acid to 0.8 or 1 Gm of potassium permanganate, were found in animal experiments to be well tolerated when applied to wound surface. The author first thoroughly cleanses the wound by irrigation with a solution of potassium permanganate-boric acid (potassium permanganate 1:4,000 in 3 per cent solution of boric acid). Then the wound is dusted with the aforementioned powder and is sutured in layers over drainage tubes. This treatment was found especially effective in the treatment of open fractures. 15 of 19 healed without fever. In 2 cases reduction had to be done elsewhere without careful cleansing of the street dirt and in 1 of them a gas phlegmon developed. Renewed reduction and application of generous amounts of the powder arrested the process. The patient was cured. The potassium permanganate-boric acid powder is especially effective in the treatment of anaerobic infections. The powder proved effective in severe cases of appendicitis, in renal operations and in cerebral abscess. While as much as 30 Gm of the powder was

used without harmful effects, such large quantities are rarely required. The powder dissolves at once in the tissue fluids after being dusted on. It does not precipitate the protein, the cellular function is not impaired, its solubility in lipoids facilitates deep penetration. The bactericidal action is intensified by the fact that tissue fluids pass toward the concentrated salt solution on the surface, this carries the pathogenic organisms toward the surface, where they are killed. The author recommends this treatment for war injuries.

**Potassium Permanganate-Boric Acid Powder in Wound Treatment**—Gyorffy states that the potassium permanganate and boric acid mixture of von Mezo represents an intensification of the effects of the two. The mixture is especially effective in the treatment of crushed contaminated and infected wounds. A culture of a platinum loopful of wound secretion of a contaminated foot wound yielded 68 bacterial colonies, three hours after application of the powder mixture only 7 colonies were obtained and after an additional three hours the culture of 5 specimens yielded not a single living micro-organism. Control experiments with boric acid powder (without admixture of potassium permanganate) disclosed that it alone is incapable of exerting an adequate bactericidal action. Control tests with pure potassium permanganate powder could not be made because of possible tissue damage. It was ascertained also how the mixed powder acts on pure staphylococci and streptococci cultures. All bacterial growth disappeared from an agar plate after the powder was dusted on whereas some organisms still survived twelve hours after boric acid alone was applied to the plates. Gyorffy concludes that the potassium permanganate-boric acid powder is valuable in the treatment of contaminated traffic and war wounds.

**Postdiphtheric Esophageal Stricture**—Postdiphtheric esophageal stricture is rare, probably because diphtheria with esophageal involvement is usually fatal. Weigand reports the history of a boy aged 9 in whom diphtheria was followed by difficulty in swallowing. After a year the condition had become severe. Roentgenologic examination disclosed extreme narrowing of the esophagus. A Witzel fistula was made, which permitted adequate feeding. A urethral cystoscope was introduced through the fistula, and with some effort it became possible to pass upward a slender urethral catheter. A thin silk thread was fastened to the catheter and pulled upward through the esophagus. The two ends, the one coming from the mouth, the other one from the fistula, were knotted together. Every second day a new thread was added and pulled through. Later the threads were replaced by a smooth cord. Finally thin Nelaton catheters were used for dilation. As their size increased, the catheters were left in place during the night. During the day only a thread was left in place. After three months of treatment the boy was again able to take fluids through the natural passage. After fourteen months of treatment all foods could again be taken by mouth, but the fistula was kept open for a while. Dilation was continued twice a week and this was followed by dilation with English bougies. Roentgenologic examination revealed that the esophagus was again normal in size. Although continuous dilation requires much time and much patience it is to be preferred to a premature surgical operation. Dilation is superior to a plastic intervention.

**Synovial and Xanthomatous Tumors**—Wengen describes a xanthomatous synovium of the elbow joint in a youth aged 18 who three months previously had knocked his elbow against an iron press. A mild painful swelling appeared on the extensor surface two days later. It subsided in two weeks but reappeared after a month. A slightly fluctuating swelling almost the size of a plum was present between the olecranon and the lateral condyle. Active and passive movements were impaired. Roentgenologic examination disclosed no pathologic changes and exploratory puncture was negative. At operation under local anesthesia a grape shaped pedicled yellowish brown tumor 7 by 5 by 3 cm. was removed from the radial side of the olecranon. It was attached to the inner surface of the articular capsule. Microscopic examination revealed spindle shaped connective tissue strands partly in reticular arrangement and traversed by capillaries. At other sites there were

xanthoma cells with hemosiderin deposits. There were no signs of malignancy. The pathologic-anatomic diagnosis was epulis-like tumor of the synovia with xanthoma formation and signs of old hemorrhages. The postoperative course was uneventful, and a follow-up examination nine months later disclosed no abnormalities. Opinions differ widely regarding synoviomias. They have been designated as gigantocellular fibrosarcomas, endotheliomas and gigantocellular sarcomas with hemosiderin. The etiology of synoviomias is still obscure, age seems to play no part, they are twice as frequent in men as in women. The knee is the most frequent site, and fingers and metatarsal joints next. Synoviomias are resistant to irradiation, making surgical treatment advisable. The synovium oscillates between fibroma and sarcoma. It greatly resembles brown tumor or epulis. If a synovium shows signs of malignancy, two thirds of those operated on die within five years. In the absence of malignant degeneration the postoperative life expectancy is not decreased. The reported case is noteworthy because of the concurrence of a synovial tumor at a rare site with xanthomatous formation. It has long been disputed whether xanthomas are true blastomas or granulation formation. Traumas, even slight ones and metabolic disturbances may be eliciting factors. At present blastomatous genesis of xanthomas is accepted beside a granuloma theory. There is so far no uniform conception regarding the mode of development or the character of synoviomias and xanthomas.

Feeding of Infants According to Bessau. H. J. Keller—p. 366

\*Therapy of Epidemic Meningitis. Gerda Oetzer—p. 374

**Prophylaxis of Measles**—Huber describes an epidemic of measles among children of German families returning from Volhynia and Galicia. The psychic shock of the migration, one sided and inadequate diet and lack of natural immunity could have been factors in the severity of the complications and the high mortality rate he mentions. Children sharing the camp with those who had contracted measles were subjected to a prophylactic treatment either with a preparation of retroplacental blood or with one of placental blood. It was observed that the retroplacental blood extract was about as effective as serum from adults, but it had the advantage that it is always available. To be more effective it may be given in considerably higher doses. The prophylactic treatment from placental blood produced somewhat better results than did the retroplacental blood extract, but the protective effect was not quite as good as earlier reports had indicated. This might be explained by the fact that the placental extract is not standardized for its prophylactic activity and that its content of active substances varies. Both substances are of value in the prophylaxis of measles, but the placental extract is somewhat more effective than the retroplacental blood preparation.

**First Case of Kala-Azar in Hungary**—According to Geldrich, the infantile form of kala-azar or Leishmania infantum occurs in the Mediterranean countries but is practically confined to the coastal regions. In Hungary it has as yet not been observed, although the disease was watched for by pediatricians and internists, particularly during the years after 1920 when numerous cases were reported in Italy. The case reported is the first encountered in Hungary. The splenomegaly, hepatomegaly, intermittent fever and the characteristic blood changes led to the diagnosis of kala-azar and the demonstration of Leishmania donovani in the splenic punctate corroborated it. Intravenous injections of neostibosan (a pentavalent antimony compound) were given beginning with 0.03 Gm and increasing to 0.07 Gm, 0.1 Gm and finally to 0.2 Gm. The injections were given every second or third day. In all the child received 1.2 Gm of neostibosan. The effects of the treatment became apparent after the fifth injection when the fever subsided. A follow up examination after seven months disclosed that the splenomegaly and hepatomegaly had completely disappeared and that the child can be considered cured.

**Therapy of Epidemic Meningitis**—Oetker presents a survey of 114 cases treated at the Magdeburg clinic since 1935. The results of meningococcic serum therapy were unsatisfactory. Blood transfusion was extremely helpful as an adjuvant to other treatments. Repeated withdrawal of cerebrospinal fluid and subsequent air filling proved of value in older children, but in children under 2 years of age the results were unsatisfactory. Chemotherapy with azosulfamide was tried but was given up because no evident results were obtained. Other sulfonamide preparations tried more recently were ulirom (dimethyl-disulfanilamide) and sulfapyridine. The therapeutic effects of ulirom did not come up to expectations, but sulfapyridine proved highly effective, even in doses which are far exceeded today. It is to be expected that the larger doses of sulfapyridine will produce even better results.

**Hemorrhagic Diathesis in Congenital Pyloric Stenosis (Hypoprothrombinemia)**—Wallgren reports case histories which suggest that the hemorrhagic diathesis of children with congenital pyloric stenosis resembles that which occurs in the newborn. The coagulation time was determined in only 1 of the cases, and in that 1 it was retarded as in hemorrhagic diathesis of the newborn. The latter is due to hypoprothrombinemia, which in turn is the result of K avitaminosis. Hemorrhagic diathesis associated with severe diarrhea or other intestinal disturbance is likewise the result of prothrombin deficiency. As a result of intestinal disturbance, vitamin K is either produced or absorbed in insufficient quantities. This led to the assumption that the hemorrhagic diathesis of pyloric stenosis is likewise a manifestation of a deficient enterogenic production of vitamin K and of hypoprothrombinemia caused by it. The correctness of this assumption was supported by the therapeutic effect of vitamin K in a case of hemorrhagic diathesis in pyloric stenosis. The rapid arrest of the hemorrhage without a simultaneous improvement of the nutritional state and in the presence of continued vomiting demonstrates that vitamin K deficiency is a factor in causing the hemorrhage. The author reports cases of pyloric stenosis in which repeated prothrombin tests demonstrated hypoprothrombinemia which could be counteracted by vitamin K. The hypoprothrombinemia and the resulting hemorrhagic diathesis are of clinical importance in pyloric stenosis. The author cites reports from the literature on postoperative hemorrhages in connection with Ramstedt's operation. Such reports have become less frequent since introduction of preoperative blood transfusions. The transfusions increase the prothrombin content and reduce the tendency to bleeding. He recommends routine administration of vitamin K previous to pylorotomy.

**Duodenal Ulcer in Infants**—Krafft reviews the literature on duodenal ulcer in infants and describes 4 new cases that came for observation at the pathologic institute of a Munich hospital. The etiology of duodenal ulcer in infants has not been explained, but the increased incidence during the summer months is noteworthy. All infants who give even the slightest indication of ulcer should be carefully examined. Search for occult blood in the stools is particularly recommended. Information should be obtained regarding the hydrochloric acid values of the gastric juice. The concurrence of ulcer development with the onset of hydrochloric acid production deserves consideration.

**Treatment of Scalds and Burns in Young Children**—Fincke reports observations on 95 children with scalds and 5 with burns. There were 26 fatalities. Complications in the form of severe dyspepsia, pneumonia, toxic impairment of the circulation, sepsis and anuria were the chief causes of death.

Dressings with 10 per cent alcohol proved most effective for heat lesions of the first degree, those of the second degree were treated with cod liver oil ointment, tannin and a burn plaster containing bismuth, alum, zinc, amyl, ethyl aminobenzoate, boric acid and Peruvian balsam. The ointment treatment can be preceded by application of alcohol. In heat lesions of the third degree the cod liver oil ointment is more suitable than tannin. The scalds of the first degree and most of those of the second degree healed without scars. The other second degree lesions resulted in slight scar formation. All scalds of the third degree healed with central scar formation, irrespective of whether cod liver oil ointment or tannin was used. Two of the third degree lesions resulted in keloid formation, which were successfully treated with radium rays.

**Interstitial Pneumonia of Children**—Giesenbauer states that in the disorder referred to as interstitial pneumonia occurring in young children and in prematurely born infants all lobes, with the exception of their anterior portions show hepatic consolidation. The cut surface varies in color from light gray to gray-red. Suppurative bronchitis and pleurisy are usually absent. Microscopic examination discloses enlargement of the alveolar framework and a peculiar exudate in the lumen of the alveoli. The enlargement is due to a dense accumulation of lymphocytes and plasma cells and to a lesser extent to an increase in fibrocytes and fibroblasts. The exudate has a honey-comb appearance and resembles fibrin but does not take the same stains. There may be seen an admixture of exfoliated alveolar epithelial cells which frequently have fatty and lipid granular inclusions and rarely inclusions of polymorphonuclear leukocytes. These observations are based on 46 cases which came to necropsy. All concern children less than 1 year old, 33 of which were prematurely born infants. There is agreement with regard to the microscopic appearances of this pulmonary disorder but no general agreement as to the differentiation from other forms of interstitial pneumonia of childhood, particularly from the congenital syphilitic pneumonia. Syphilitic congenital pneumonia and the interstitial (plasmacellular) pneumonia are not identical in their microscopic characteristics. The peculiar type of exudate which is regularly encountered in the interstitial pneumonia is never seen in congenital syphilitic pneumonia. The thick concentric increase in fibers about the arterial and venous branches which is seen in the syphilitic form is never observed in the interstitial pneumonia. Noteworthy also is the comparatively slight increase in collagenic fibers in the interstitial form. The cause of interstitial pneumonia is unknown. Various types of bacilli have been encountered. It is not certain whether the disorder is infectious and whether it should be designated as pneumonia. The first case reported (Feyrter) was identified as "lymphoplasmocytoma," and in the more recent reports it is referred to as diffuse plasmocytosis of the lung, rather than interstitial pneumonia.

Stability of Iodine in Iodized Salt A G Van Veen—p 2637  
Difficulty of Classifying Tumor of Humerus W M Pruijs—p 2641

**Bacteria of Newcastle Dysentery Group in Dysentery Patients in Netherlands East Indies**—According to Esseveld and his collaborators the mucous and bloody stools of patients with mild bacillary dysentery yielded on culture forming bacteria which, according to comparative examination with the Manchester type of the Newcastle dysentery bacteria. The identity claimed by Scott and Boyd for the antigen of the Newcastle dysentery organisms with that of the type described by Boyd (Boyd 88) could be corroborated by Esseveld and his associates. In 64 cases of dysentery on the East coast of Sumatra the feces yielded a bacterial flora of the Manchester type and no other pathogenic bacteria. Simultaneous bacteriologic tests on feces from patients with dysentery never disclosed the Manchester strain. In a series of tests the original Newcastle type was encountered.

## Book Notices

**Bellevue in France** Anecdotal History of Base Hospital No. 1 By Anne Tjomsland M.D. Cloth Price \$2.50 Pp. 251 with 82 illustrations New York: Froben Press 1941

The publication of this book is timely. It should attract all who are interested in military hospitals in the war area. The Bellevue unit operated as Base Hospital No. 1 in Vichy, France, from March 12, 1918 to March 5, 1919. The author, avoiding all technical details, portrays the operation of the unit in a delightful manner with many anecdotes, photographs and maps. Fortunately, she had not only an unusual appreciation of the psychology of the hospital personnel, patients and the French people but also the ability to transmit her impressions to the reader.

One gains the impression that the friendliness of old Bellevue as expressed by an outgoing patient, "This is a friendly place," must have prevailed at Vichy, for the spirit of service prevailed. No task was too difficult, no hours of labor were too long if the comfort and welfare of the patients required it. The personnel and convalescent patients did new strange tasks remarkably well. One learned that when human life is to be salvaged and suffering relieved the best in all of us becomes evident. "There was not much need of discipline; we were learning that when mankind is pushed to extremities its behavior on the whole is pretty decent."

The unit, which was organized in the autumn of 1916, was accepted by the War Department in June 1917. The equipment, valued at more than \$125,000, was purchased by funds donated by friends. It sailed on the *Olympic* Feb. 26, 1918, docked at Liverpool March 5, reached Le Havre March 8 and arrived at Vichy March 12. Vichy, or Aquis Calidis as it was called by the Romans, had been developed by them as a large fashionable water resort. Many years later Napoleon III restored it to its Roman grandeur as a famous summer resort. Elegant hotels were established with other necessary buildings and streets. Its railroad facilities and numerous hotels made it desirable as a location for a general hospital. The Bellevue unit first occupied ten hotels, during June and July ten more were added. During the week of July 16-22, 1,733 patients were admitted; in October, 3,206, the total treated was 16,077. Vichy became a hospital center, and Base Hospital No. 1 was joined by No. 19, No. 76, No. 115 and No. 109 and Convalescent Camp No. 9.

The staff of the hospital, which was organized for 500 patients but was treating several times that number, was depleted by calls for surgical teams needed in the combat area. With the author we visit such hospitals; we see the condition of the soldiers coming from the indescribable filth and mud of the battlefield and sense their frightful fatigue and near exhaustion.

Finally, "It seems that we had lived somewhere else, long ago, had gone through a breath-taking interval of startling events, blinding toil till you almost killed yourself, as well as spirited pleasures—and now we were going back to begin all over again. We should forever have a horror of war. But we also felt dissatisfied with civil life as we had known it."

**Laboratory Diagnosis of Protozoan Diseases** By Charles Franklin Craig M.D. M.A. F.A.C.S. Cloth Price \$4.50 Pp. 349 with 38 illustrations Philadelphia: Lea & Febiger 1942

This book is written to supply a work devoted entirely to laboratory methods for the diagnosis of diseases caused by protozoan parasites. It is the expressed desire of the author that it may be of real worth to physicians conducting their own clinical laboratories and to workers, especially technicians, in various laboratories preparing material for the diagnosis of these diseases. There are six parts devoted to the laboratory diagnosis of amebiasis and flagellate infections, leishmaniasis, trypanosomiasis, coccidiosis, malaria and balantidiosis. The laboratory methods in each part are given with exhaustive thoroughness. For example, under amebiasis there are chapters devoted to the morphology of the parasites, the collection and preparation of materials for examination, the diagnostic value of cultures, complement fixation and animal inoculations. Some of the methods described will probably be of more interest to the research worker than to the physician or technician interested in diagnosis but the confusion that might result from

the inclusion of so many technical variations is largely, if not entirely, eliminated by the "critique of diagnostic methods" which is appended to the consideration of each group of diseases. Specialists will probably question the criteria for including or excluding certain methods. Such criticisms, however, are matters of opinion and there is no doubt that the author has exhaustively and accurately presented the important laboratory methods. The book will undoubtedly be of value to laboratory workers.

**La anestesia general intravascular** Trabajo galardonado con la medalla de oro de la R. A. de medicina Madrid. Por el Dr. E. Perez Castro. Paper Pp. 95 with 69 illustrations Madrid: Ediciones Morata 1941

**El nivel motorico (edad motora)** Por el Dr. César Juarros médico-otor de la Escuela nacional de anormales. Paper Pp. 111 with 7 illustrations Madrid, Barcelona & Buenos Aires: Ediciones Morata 1941

**Diagnostico y clinica de la tuberculosis infantil** Por el Dr. Georg Simon, médico jefe del Sanatorio infantil de Aprath. Traducido por los Doctores R. Navarro Gutierrez y F. Paz Espeso, directores de los dispensarios antituberculosos centrales de Buenavista (Madrid) y Guadalupe (Barcelona). Paper Pp. 111 with 44 illustrations Madrid: Ediciones Morata 1941

**La esterilidad en la mujer. ¿Qué causas la originan?** Por el Dr. Vital Aza, director del Sanatorio quirúrgico y Clínica de maternidad Santa Alicia. Madrid. Paper Pp. 110 Madrid: Ediciones Morata 1941

**Difteria. Epidemiología, diagnóstico, clínico, tratamiento** Por el Dr. J. de Eleizegui Steyro. Paper Pp. 122 with 14 illustrations Madrid: Ediciones Morata 1941

**Personalidad y carácter. Estudio crítico** Por el Prof. Dr. M. Bañuelos, catedrático de la Universidad de Valladolid. Paper Pp. 127 Madrid, Barcelona & Buenos Aires: Ediciones Morata 1941

**La prostata y sus enfermedades** Por los Dres. A. y E. de la Peña. Paper Pp. 93 with 16 illustrations Madrid: Ediciones Morata 1941

Perez Castro's book made the author the winner of the gold medal of the Royal Academy of Medicine of Madrid and of the degree of academic member of the academy, which the latter offered by contest, for the best article on intravascular general anesthesia. This book contains chapters on the history of intravascular anesthesia and substances used, with special reference to the pharmacology, experimental and clinical results and accidents and contraindications of evipal soluble. The book ends with eight pages of bibliography.

Juarros' book is the result of observations of the author, who is a fellow of the Royal Academy of Medicine of Madrid and the head of the National School for abnormal children of that city. This book purports to show the relations between motricity—the motor state—and mentality in children. There are chapters on the value of Osebetzky's tests for intelligence and the motor state and of Osebetzky's collective tests for determining the motor state in relation to chronological age.

Dr. Simon's book is the result of observations as the head of the sanatorium for Diseases of Children in Aprath. The book is a compilation of several articles previously published by the author in German and a translation of the articles from German into Spanish which was carried on by Drs. R. Navarro Gutierrez and F. Paz Espeso, heads of the antituberculosis dispensaries of Madrid and Guadalupe respectively. There are different chapters on the frequency, diagnosis, differential diagnosis and clinical forms of pulmonary tuberculosis in children and also chapters on the complications and sequels of the disease.

Vital Aza's book issued from his work as head of the Santa Alicia Maternity Hospital of Madrid. The book contains chapters on the causes and social importance of sterility in women. There are several chapters on frigidity and the mechanical, functional, constitutional, endocrine, psychological and pathological factors of sterility. There are also chapters on maternity and foster motherhood, and on the role of syphilis and tuberculosis in sterility.

Eleizegui's book issued from experience as an officer of the Medical Department of Public Health of Madrid. This book is devoted to the discussion of the problems of epidemiology, diagnosis, clinical forms, therapy and prevention of diphtheria. The book ends with six pages of bibliography from modern literature.

Bañuelos' book is a review of various theories on heredity, physical, psychic, sexual, environmental, educational and other factors which are in relation with personality and character and a critical study of all typologic classifications or

personality and character. It purports to show the psychobiologic roots and fundamentals of personality and character, the causes of radical changes and the feasibility of modifying changes and improving personality and character by determination, perseverance and good advice and example. Other aspects of personality and character also are discussed.

Peña's book purports to show modern trends which are of practical clinical value for the diagnosis and therapy of diseases of the prostate. There are several chapters on general study of latent, acute and chronic diseases of the prostate, differential diagnosis of fever from retention of urine, causes of diseases of the prostate and surgical therapy. The book ends with a chapter with formulas and therapeutic indications of use in clinical practice and a page of bibliography on the subject.

**Textbook of Embryology** By Harvey Ernest Jordan, M.A., Ph.D., Sc.D., Professor of Anatomy and Director of the Anatomical Laboratories, University of Virginia, Charlottesville, and James Ernest Kindred, M.A., Ph.D., Professor of Anatomy, University of Virginia. Fourth edition. Cloth. Price, \$6.75. Pp. 613, with 501 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1942.

First published in 1926, this textbook for medical students has now undergone its first extensive revision. An important addition to the descriptive material, which necessarily forms the bulk of the text, is much recent experimental and comparative material. This in part has been incorporated in the text, and in part is summarized in fine print at the end of the appropriate descriptive sections. Such material is particularly welcome in a field which is being actively investigated and in which new and significant contributions are continually being made. As is almost inevitable, some sections are treated more adequately than others. Since human development is primarily the object of the text, it would seem that in the discussions of early development, especially in presomite stages, more emphasis might be placed on the magnificent recent contributions to early primate development from the Carnegie Institution. Similarly the most basic aspects of fetal physiology, especially with respect to the respiratory and nervous systems, might well be included, perhaps even as an integral part of the text, which would be thereby enlivened. In this connection it is surprising that Windle's monograph on the highly interesting and important subject of fetal physiology is not mentioned. Nevertheless, those who have used this textbook for medical teaching will welcome this new edition, which is attractively bound and printed. Many new and useful illustrations have been added, but many of the retained line drawings are as crude and unattractive as ever, and some of the halftone reproductions are not up to the high standard set by modern morphologic textbooks.

**Medico Surgical Tributes to Harold Brunn**. A Series of Essays on Various Aspects of Surgery and Medicine Written by His Pupils and Friends. Cloth. Price, \$6. Pp. 571 with illustrations. Berkeley & Los Angeles: University of California Press, 1942.

A well deserved tribute to one of the leading surgeons of the Pacific Coast area becomes available in this volume from the University of California Press. In his statement in the book the editor of *THE JOURNAL* says "In the social, civic, educational and professional aspects of medicine in San Francisco, Dr. Harold Brunn has been a leader. His numerous contributions to the literature of scientific medicine are evidence of the place he has made for himself as a practitioner of medical science. Nevertheless he has found time in the midst of all this activity to stimulate innumerable young men, who hail him as their preceptor. Thus he has truly fulfilled the requirements necessary to be listed among the builders in medicine. He has built educational institutions, laboratories of research, hospitals and, above all, young men."

The book itself makes apparent the well merited character of the tribute. Statements from the president of the university, the dean of the medical school and its professor of surgery are supplemented by fifty-three essays running the gamut of progress in every field of medicine and surgery. Most of America's great surgical leaders are represented, and they are supplemented by reports of technical research in the laboratory and statements in the field of experimental medicine and the public health. The volume is supplemented by a bibliography of the writings of Dr. Brunn. It is printed and bound in a style adequate to its quality.

**Neuroanatomy** By Fred A. Mettler, A.M., M.D., Ph.D., Professor of Anatomy, University of Georgia School of Medicine, Augusta. Cloth. Price, \$7.50. Pp. 476, with 337 illustrations. St. Louis: C.V. Mosby Company, 1942.

This textbook is intended for medical students beginning the study of neuroanatomy. The first half is devoted to the gross morphology and topography, and the second to the microscopic anatomy of the nervous system (the author uses the phrase "neural system"). In both parts he has kept in mind the future needs of the student in his clinical studies and has also endeavored to clarify those aspects in which clinical students and interns have shown evidence of misunderstanding. The illustrations are worthy of special comment. They were made specifically for this book from original material prepared by the author. Schemas from other sources have been redrawn. Obviously no pains have been spared to make the illustrations as effective as possible in relation to the text. In addition to the aims mentioned the author has endeavored in the first part to emphasize aspects of importance in practical medicine and in the second part to help in establishing a sound functional point of view. He characterizes the work as a "bare outline for the fuller study required by the special fields of medicine." However, the average medical student in his clinical years rarely shows evidence of having mastered more than a small part of the ground covered in this volume. Thus the labor involved in organizing the bibliography, which comprises several thousand references and fills fifty-three pages, may not receive much appreciation. However, the book will be useful to many long past the undergraduate stage and they, at least, may find the bibliography helpful. This volume is a worthy addition to the various other excellent textbooks now available on the subject.

**Economics of Social Security: The Relation of the American Program to Consumption, Savings Output, and Finance** By Seymour E. Harris. Associate Professor of Economics, Harvard University, Boston. Cloth. Price \$5. Pp. 455. New York & London: McGraw-Hill Book Company, Inc., 1941.

Every phase of the economics of social security is exhaustively treated, and the relation of each phase to the most recent economic developments is discussed. The possible reactions of the large financial operations involved and their possible effects on savings, investment, wages, interest, price, consumption, finance, inflation and employment are discussed as related to all stages of the industrial cycle. The possibility of failure to meet security obligations in case of war is recognized. So thorough and basic is the work that its reading is essential to any real understanding of the multitude of problems involved. The reading is not easy. It assumes a familiarity with the writings of Keynes, Hansen, Wickseil, Joan Robinson and Pigou as well as of their predecessors, and none of the writers mentioned are easy of comprehension by those unfamiliar with economics. Any one engaged in the management or interested in the operation of social security will find that the effort required to master the book will be repaid by added ability to understand the problems involved.

**Visual Outline of Psychiatry** By Leland E. Hinsie, M.D., Prof. of Psychiatry, College of Physicians and Surgeons, Columbia University, New York. Oxford Medical Outline Series. Cloth. Price \$2. Pp. 103. New York, Toronto & London: Oxford University Press, 1941.

This little volume is one of a series of short outlines covering various aspects of medicine. The present psychiatric outline is systematically carried out and consists of five parts, the last being the glossary and index. The first part of the book deals with the organization of the mind. The second and largest part of it covers the psychiatric syndromes, including the psychoses, neuroses and psychoses, and the fourth part covers intellectual deficiency. As the latter part is only about three pages long it is obvious that the problem of mental deficiency is much sketchily done, a criticism that can be leveled at the whole volume. For instance, psychopathic personalities are covered in what amounts to one page. There is a definition of it for about half of the section, and a four line description of its manifestations, one line on the course, and half a dozen lines on treatment. It is difficult to see in just whose library this would fit. It is obviously intended for the student and is heavily interleaved with blank pages for note taking. It is a fairly good glossary appended to it, but it can neither nor adequately supplement conventional textbooks.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT HOWEVER REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

### DETERMINATION OF PATERNITY OF A NEWBORN CHILD

To the Editor—Will you please send me information about any legally accepted method of determining the paternity of a newborn child? One of my patients is desirous of this information as soon as possible and I would appreciate your cooperation. M D Canon City Colo

ANSWER—Knowledge of the A-B group or the M-N type of blood of parents makes it possible to predict which blood groups or type children from this mating may or may not be. In the determination of the paternity this information can be used only as negative evidence unless all males, other than the one person in question, can be eliminated from consideration. If all men concerned in such paternity problems were falsely accused, the determination of the A-B group of mothers, presumed father and child gives the man in question a 16 per cent chance of being eliminated. An additional 18 per cent chance of elimination may be had by the determination of the M-N types. Thus with the determination of both A-B and M-N the chances of exclusion are between 35 and 40 per cent. Such evidence is not universally accepted by courts. However, New York, Wisconsin and perhaps other states have enacted laws authorizing the courts to order such blood grouping tests in cases of questioned paternity. Details of technic and complete lists of possible groups and types in children born of parents with varied combinations of groups and types may be had in several standard works, such as *Diseases of the Blood* by Kracke, published by Lippincott, *Textbook of Clinical Pathology* by Kracke and Parker, published by Williams and Wilkins and *Blood Groups and Blood Transfusions* by Wiener, published by Thomas.

### ANTIPERSPIRANTS AND DEODORANTS

To the Editor—I have been consulted by some high school girls about the advisability of shaving under their arms using deodorants and the kind of deodorant if recommended.

J P McGowan M D Horton Iowa

ANSWER—If done carefully, there is no harm in shaving the axillary hair. Not all young girls need assistance from antiperspirants and deodorants. Their tendency to make much of slight difficulties of this sort should be discouraged, for an olfactory neurosis can cause much misery and is particularly hard to overcome.

Antiperspirants and deodorants are closely related, and it is hard in some cases to separate one from the other. The first measure of protection against body odor is frequent washing with soap and water to remove the products of perspiration which, by decomposing furnish most of the odor. After this a mild lotion may be applied, such as salicylic acid 24 Gm, benzoic acid 48 Gm and 50 per cent alcohol to make 120 cc, dabbed on the axillas frequently.

Another somewhat stronger lotion is solution of formaldehyde U S P diluted 1:100 in alcohol. This cannot be used so often. Once or twice a day is often enough, but its effect is more lasting. Oxidation of the products of sweating is often tried by applying a wine red solution of potassium permanganate in distilled water. It is efficient but, if used in too great strength, turns the skin brown. Another oxidizer is the dusting powder recommended by Goodman (*Cosmetic Dermatology*, New York McGraw Hill Book Company, 1936, p 438): zinc peroxide 1 Gm, benzoic acid 1 Gm and talc to make 100 Gm. Other powders recommended by the same author are solution of formaldehyde 1 cc, thymol 1 Gm, zinc oxide 32 Gm and talc to make 100 Gm or magnesium carbonate 32 Gm finely powdered alum 32 Gm and talc to make 100 Gm. These may be dusted on after the bath. Goodman presents many other formulas.

In cases of pronounced axillary hyperhidrosis, stronger measures are necessary. Aluminum chloride introduced into American dermatology by Stillians in 1916 (*The Control of Localized Hyperhidrosis* THE JOURNAL Dec 30, 1916 p 2015) is the strongest of these, effective in most cases checking the excess perspiration and keeping it in check by moderate use. As the author warns, certain precautions are necessary to success. The 25 per cent aqueous solution recommended is acid and irritating

to clothing, so that one must use care that the skin of the part has dried before putting on the clothes. If applied too often, it may act as a primary irritant. The author suggests applying it once every third day. After the effect has been obtained an application once a week is usually enough to maintain the effect. It is very important to avoid washing the part with soap just before applying the lotion, for soap or any alkali counteracts its effect.

The most effective measure against hyperhidrosis is roentgen therapy. Unfiltered radiation may be given once a week in a dose of 75 roentgens, or once a month 225 roentgens may be administered. Two to six months' treatment may be necessary to effect a satisfactory decrease of sweating. When a decided decrease has been obtained, treatment should cease, for usually there will be a further lessening after the treatments have been discontinued. Later the effect will be less, but recurrences are not common (MacKee, G M. X-Rays and Radium in the Treatment of Diseases of the Skin, ed 2, Philadelphia, Lea & Febiger, 1927, p 547). The use of any irritant during or for three weeks after the end of the course of treatment is strictly enjoined. Soap and water followed by a bland dusting powder should be all that is allowed.

Persons who wish to be free from body odor should avoid excessive participation in foods containing onions or garlic. Eller (*Body Odor*, M Rec 154 167 [Sept 3] 1941) lists other foods and a number of drugs which may contribute odor to the perspiration.

Many persons advocate perfume to cover the body odor. Some perfumes, as Eller says, decompose under the influence of the perspiration and intensify the body odor. Care must be taken to choose one that will improve matters without having to be used in excess. Heavy perfume is as repugnant to some people as body odor.

### TREATMENT OF ACUTE MORPHINE POISONING

To the Editor—Will you please indicate briefly the modern treatment of acute morphine poisoning? I did some research work on this subject thirty five years ago. The results of that work demanded a radical change in the old treatment. That is why I make the request.

Neol Kitchens M D, Warm Springs Ga

ANSWER—Morphine is readily absorbed from the stomach and intestine and is then excreted again into the stomach, where it is again absorbed. As much as one third of the morphine given hypodermically has been recovered from stomach washings. It is for this reason that in the treatment of acute morphine poisoning the stomach should be washed.

As soon as the patient is seen the stomach is washed repeatedly with a solution of potassium permanganate, 0.5 Gm of permanganate to the liter of water. This oxidizes the morphine to oximorphine, which is harmless. If permanganate is not available, a 5 per cent solution of tannic acid or a strong infusion of tea may be given. This forms an insoluble compound with the morphine and thus prevents absorption. Magnesium sulfate may be given to hasten the removal of the morphine from the intestine. Caffeine, either by mouth, intravenously or as a strong hot coffee enema, is a physiologic antidote. Nikethamide is given for stimulation. The patient is kept warm, and most authorities feel that the patient should not be allowed to go to sleep. If the patient lives for twelve hours following the ingestion of the morphine, the prognosis for complete recovery is favorable.

### INFLUENCE OF FATIGUE ON ANEMIA

To the Editor—Are there reports in the literature of scientifically controlled experiments on the role of fatigue either acute or chronic in the production or maintenance of anemia? I have noticed in the past few years since I have been stressing rest that secondary anemias respond much more readily.

L. A. Crowell Jr M D Lincoln N C

ANSWER—After brief exercise there is an increase in the erythrocytes in the peripheral blood apparently because of release of stored red cells into the circulation. After prolonged exercise in dogs there is an increased destruction of erythrocytes with slight lowering of the erythrocyte count and hemoglobin content of the blood. This is accompanied by an increase in reticulo-cytes and hyperplasia in the bone marrow.

It is quite possible that a patient with anemia due to blood loss or deficiency might recover more rapidly when at rest than while performing hard work.

## A PATERNITY PROBLEM

To the Editor—A young married woman has a regular twenty-eight day cycle. She usually can tell by slight cramps when ovulation takes place. Just before marriage (a sudden event) she had a normal period. On the sixth and eighth days of her cycle she had intercourse. On the fourteenth day she noted the usual symptoms of ovulation. On the twenty-first day of the cycle she was married and had intercourse with her husband (a different man). The following menstrual period did not take place. The patient is worried that she may be pregnant by the first man rather than by her husband. Unless I can offer her definite assurance to the contrary I feel sure she will resort to illegal abortion. My own reading and knowledge indicate that she is more likely pregnant by her husband. I should appreciate a prompt reply so that I may avert a possible tragedy.

M D

ANSWER—The exact day of ovulation in women cannot be determined with certainty except in a few who have characteristic intermenstrual pain. Daily vaginal smears may be used to determine ovulation in some women, but generally there is nothing characteristic of the process. Ovulation usually occurs fourteen days before the following menstrual flow. This interval appears to be fixed, but the lapse of time between the onset of bleeding and subsequent ovulation may vary considerably. Furthermore, it is known that an ovum usually lives only about twenty-four hours and seldom survives more than forty-eight hours. Spermatozoa, however, generally are capable of fertilization for forty-eight hours and in some instances perhaps longer. However, nearly all these data are based on what occurs in animals, hence they may not be entirely applicable to human beings. Theoretically, coitus on the twenty-first day should not lead to fertilization in a woman who has a twenty-eight day cycle, but this does not mean that it is impossible for a woman with a fairly regular twenty-eight day cycle to ovulate on the twentieth or the twenty-first day. If ovulation does take place late in a menstrual cycle and pregnancy does not supervene, the onset of the following period is generally delayed.

In order for the first man to have impregnated the patient one must infer that ovulation occurred some time between the fifth and the ninth day of the cycle or that this man's sperm retained their ability to fertilize an ovum for at least six days.

Since there are so many uncertain factors concerning ovulation in the human being and since it is definitely possible that the husband may be responsible for the pregnancy, the patient should not have her pregnancy terminated.

## PROBABLE SYPHILITIC PORTAL CIRRHOSIS

To the Editor—A woman aged 41, who states that she had a positive Wassermann reaction for several years and has received forty-six injections of neoarsphenamine and at least an equal number of bismuth injections, complains of a gradual enlargement of her abdomen over a period of six weeks. The patient is thin. There is no dizziness, cyanosis or jaundice. The pupils are round and react. The nose and throat are normal. The heart and lungs are apparently normal. The abdomen shows signs of fluid, no masses are palpable, either liver or spleen. There are external and internal hemorrhoids, and edema of both legs is present. The urine is normal except for a trace of albumin. A gastrointestinal roentgenologic study revealed nothing of note except the presence of fluid in the abdominal cavity. A gallon of clear fluid was obtained by paracentesis and, by all laboratory procedures, proved to be a transudate. The Kline reaction was weakly positive and the Kolmer complement fixation reaction strongly positive. The albumin globulin ratio was 1:7 and a Takata-Ara test was positive. There is a secondary anemia. In view of the probability that this is a syphilitic cirrhosis, is the use of bismuth and arsenic compounds contraindicated? What would be the proper course of treatment for a case of this type?

B E Lachman, M D, Oil City, Pa

ANSWER—We would agree that the patient has a portal cirrhosis, whether it is syphilitic or not is difficult to say. No mention is made of an alcoholic history. The patient has already had sufficient antisyphilitic therapy in the form of arsenicals and bismuth compounds. While, years ago (A Therapeutic Paradox, *Am J M Sc* 164:415 [Sept] 1922), pointed out that in syphilitic hepatitis the patient may apparently respond brilliantly to the arsenical therapy only to get worse and die later of a cirrhosis.

Certainly the physical findings, as well as the reversed albumin globulin ratio 1:7 and the positive Takata-Ara, would speak in favor of a portal cirrhosis.

In the way of therapy there would be no harm in the use of potassium iodide, in fact, it might be of definite value, and, if any heavy metal is employed, reliance should be put on soluble mercury injections, e.g. mercuric succinimide intramuscularly three times a week.

Paracentesis should be done as indicated. The patient should be allowed no alcohol. Her diet should consist principally of carbohydrates, though milk is allowed. Fatty foods, eggs and meat should be restricted. Salt in the diet should be restricted, and saline cathartics are in order.

## EDEMA OF EYELIDS IN SINUSITIS

To the Editor—What is the mechanism responsible for edema of the eyelids in sinusitis? Is it an allergic manifestation or mechanical resulting from congestion? For years I have suffered from ethmoiditis and have tried everything recommended—roentgen rays, vaccines, Penicillin and other local treatments, surgery (turbinectomy, ostiotomy, mucous resection, anterior and posterior ethmoidectomy—all on the left side) but not complete exenteration. For about a year I have had frequent attacks of edema of the right eyelid, which come on at night and slowly subside. These are getting more frequent, more severe and troublesome, and now there is always slight edema between attacks. There is rather profuse discharge from both nostrils of greenish yellow pus, the culture shows *Staphylococcus aureus*. Autogenous vaccine does not relieve. What is the prognosis and best treatment? Should radical surgery be resorted to?

M D, Hollywood, Calif

ANSWER—Without examining the patient, one's answer to the above query is apt to be incomplete. The most likely cause of the edema of the eyelids is a chronic conjunctivitis secondary to an ascending infection from the nose by way of the lacrimal passages. There may be an allergic factor present. In fact, in many cases of protracted ethmoiditis the chronicity is due to a secondary infection based on progressive allergic changes. It is not likely that a low grade orbital periostitis secondary to sinusitis would come and go just in the manner described. This would apply also to congestive changes in the orbit. Treatment should be dependent on the judgment of a competent rhinologist. Every attempt including the use of cutaneous tests should be made to determine the presence of an allergic factor and to remove it if possible. Because there seems to have been a fair trial of the more conservative measures, a thorough exenteration of the ethmoid labyrinth, preferably by external approach, should be seriously considered. If there is no other sinusitis present such an operation, well done, offers a minimum of risk and a good possibility of satisfactory relief.

## SENSITIVITY TO DUST AND VACUUM CLEANERS

To the Editor—Many of my patients are sensitive to house dust. What type or make of vacuum cleaner will cause the least dispersion of dust particles and bacteria into the air? Is the so called tank type of cleaner more efficient as an air filter than the conventional upright models?

M D, New York

ANSWER—All the vacuum cleaners at present on the market cause some dust dispersion. However, the tank type, if well made, is more efficient than the type with the unenclosed bag. While some of the tank types have cloth filters which are advertised as highly efficient, the filtering efficiency is far from good. It is therefore advisable for the patient sensitive to dust to be out of the house while vacuum cleaning is being done. If this is not possible, the patient may wear a mask.

## COMBINED VACCINATION OF CHILDREN

To the Editor—In the use of combined diphtheria toxoid and pertussis toxoid, a dose of 1 cc to be repeated in three months is advised. Would there be any harm in either vaccinating or giving the pertussis vaccine during that three month period?

Samuel J Bolonik, M D, Chicago

ANSWER—Harm should not result from the concurrent program to vaccinate against smallpox or to administer pertussis vaccine within the period specified. However, the difficulty in immunization procedures should be properly spaced to avoid the possibility of accumulated reactions.

It would not be advisable to inject immunizing substances for other diseases while a local reaction from smallpox vaccination was present because of the added discomfort that the patient might experience.

## CORBUS-FERRY CUTANEOUS TEST FOR GONORRHEA

To the Editor—What is the value of Corbus-Ferry gonococcus filtrate as a diagnostic procedure in gonococcal infections?

William F Putnam, M D, Lynn, Mass

ANSWER—The value of the cutaneous test with gonococcus filtrate (Corbus-Ferry) is questionable. Even in the hands of those who have had a great deal of experience with it a definite diagnosis cannot be established. The test may be an aid in the diagnosis of gonococcal infection but the clinical history and culture are the best criteria. The filtrate is of no therapeutic value and has been ruled out acceptable for use by the Council on Pharmacy and Chemistry of the American Medical Association.

## THE TREATMENT OF BURNS IN WARTIME

HENRY N. HARKINS, M.D., PH.D.

DETROIT

The problem of thermal injuries is as old as recorded history. Even before fire had been harnessed to man's use the danger of burns from molten lava, forest fires and hot springs was constantly present. More recently the accidents of wartime have greatly increased the importance of thermal injuries. It is reported that 60 per cent of the casualties at Pearl Harbor were burns.

The treatment of war burns requires an adequate knowledge of the management of peacetime injuries coupled with an understanding of several of the distinguishing features of wartime burns. The present conflict has produced several unusual injuries not previously seen in large numbers, e. g. the "airman's burn," the phosphorus burn and the burn contaminated by oil and sea water. These special types will be discussed later in more detail.

The adequate management of any burn includes a careful cooperative effort in two directions, namely: (1) the general treatment of the patient and (2) the local treatment of the burned area. The first of these is probably more important than the second, as it is of little avail to have a clean, well dressed burn but a dead patient. These two endeavors will now be considered more fully, after which a special discussion will be given of war burns.

### GENERAL TREATMENT OF THE PATIENT

**Shock**—From the practical standpoint, no differentiation need be made between primary and secondary burn shock. Usually by the time the patient is admitted with a severe burn true secondary, or traumatic, shock exists and it should be managed according to well established principles.<sup>1</sup> In fact, the only difference between burn shock and shock due to other types of trauma is that in the former the degree of hemoconcentration is much greater. It will be shown that this actually makes the treatment simpler, since the extent of hemoconcentration is an excellent therapeutic guide.

One of the first things to do when a severe burn occurs is to diagnose and to treat shock. Estimates have placed the incidence of burn deaths which are due to shock at from 60 to 75 per cent of all burn deaths. Wilson<sup>2</sup> in summarizing 80 burn cases found

that death from shock occurred in 63 per cent. Seeger<sup>3</sup> reported a percentage of 64 and Klotz<sup>4</sup> of 70. Atkins,<sup>5</sup> in discussing the burned patients evacuated from Dunkirk, said "Secondary shock is the most serious factor in burns and is responsible for 60 per cent of the deaths occurring in this condition."

The pathologic physiology of burn shock is extremely complicated. Various theories in the past have attributed shock to toxic, nervous, septic and fluid loss factors. At present it seems likely that all these influences are at work but probably at different times. Just as with diphtheria a patient may die early of laryngeal obstruction and late from myocardial damage, so with burns at different stages during their course, fluid loss, toxemia and sepsis may have a role. Figure 1 demonstrates such a concept schematically.

The early stages of shock undoubtedly include the following essential elements of disturbed physiology. The local thermal trauma causes a local capillary injury with regional loss of plasma-like fluid. This local plasmorrhhea is both into the damaged tissues and from the burned surface as "weeping." Later, owing to tissue metabolites set loose in the damaged area or to resultant hypovolemia, there is a generalized loss of plasma-like fluid from capillaries remote from the burned area. The amount of plasma lost is of especial consequence and may equal several liters. Secondary to this loss is a reduction in blood volume, cardiac output and blood flow with associated hemoconcentration. The correction of this condition before dangerous and irreparable anoxic tissue damage and irreversible generalized increased capillary permeability occurs forms the prime element in the treatment of burn shock. Other changes are of essentially secondary importance. Chemical alterations in association with burns include a decrease in plasma sodium, plasma chloride and plasma proteins as well as an increase in plasma potassium, plasma magnesium and plasma bilirubin in certain instances. The chemical aspects of burns have recently been reviewed by Lam,<sup>6</sup> Tenery<sup>7</sup> and myself.<sup>8</sup>

The treatment of burn shock can be discussed under four heads:

1. **Supportive Measures**—These include rest, quiet, elevation of the foot of the bed, warmth and use of sedatives, stimulants and vasopastics. Such remedies may be useful but are essentially symptomatic and do not get at the source of the trouble.

2 Oxygen Mutch<sup>9</sup> formulated a simple rule for remembering the percentages of oxygen furnished by different methods. He pointed out that the percentages of alveolar oxygen obtained are multiples of fifteen.

Normal percentage of alveolar oxygen, 15

With nasal catheters, 30

With tent (usual), 45

With tent (extreme), 60

With B L B mask, 90

The more serious the burn, the higher the percentage of oxygen that is advised. In extreme instances the B L B mask, with its capability of giving 90 per cent oxygen or more, should be applied. The adequate and continued control of anoxia is important in any type of shock.

3 Adrenal Cortex The use of this substance in synthetic or in extract form is still in the experimental stage but may prove of value. It is common knowledge that the cortex of the adrenal gland is essential to life and that animals with a deficient adrenal cortex are unusually susceptible to procedures which commonly produce shock. The converse of this, namely that the administration of adrenal cortex extract is useful in the treatment of burn shock, is far less well established. This subject has recently been reviewed by Harkins,<sup>10</sup> Loeb,<sup>11</sup> and Kendall.<sup>12</sup> As Kendall pointed out, there are several substances present in the adrenal cortex with varying and at times opposing actions. Much confusion has arisen from carelessly considering any or all of these as adrenal cortex extract. One of the most encouraging of the well documented reports on the use of these substances in the treatment of burn shock is that of Rhoads, Wolff and Lee.<sup>13</sup> These authors found adrenal cortex extract of value in preventing fluid loss in cases of severe burns.

4 Plasma and Other Fluids Fluid replacement therapy is actually the most important element in the treatment of burn shock. Plasma is lost in large amounts, and large amounts of plasma should be replaced. Whole blood is useful when plasma is not available, but its contained erythrocytes are superfluous.

Fig 1—Chronological course of a burn (from Harkins<sup>10</sup>)

All burned patients should be kept in adequate chloride balance, but usually 1,000 cc of isotonic solution of sodium chloride a day (10 Gm of sodium chloride) is

sufficient unless the patient is vomiting or otherwise losing chlorides in abnormal amounts. Dextrose should be given in large amounts to protect the liver, but its administration should be by mouth whenever possible. Complete reliance on crystalloid solutions for intravenous fluid replacement therapy for burn shock is fallacious. Plasma, then, is the best means of replacing the fluid loss due to thermal trauma.

Fig 2 (case 1)—Burned areas of patient W K. According to Berkow's formula, the total burned area was 20 per cent of the body surface (head 3 per cent, hands 4.5 per cent, arms 7.5 per cent and back 5 per cent).

The use of plasma should be quantitative. There is no more reason for always giving a shocked patient a pint of plasma than for always giving a diabetic patient 10 units of insulin. Calculation of the dose of plasma should be individualized for each burned patient. For this purpose, the aid of one or more of the following five guides should be invoked.

Method 1 (clinical method) As advised by Rhoads, Wolff and Lee,<sup>14</sup> plasma should be given by continuous intravenous drip transfusion to all seriously burned patients. The rate of flow should then be adjusted so as to maintain the peripheral circulation continuously. This is evidenced better by a control of the blood flow than by a normal blood pressure or pulse rate. Since the estimation of the blood flow is often difficult other methods, as listed hereafter, may be more suitable for calculating the dose of plasma. A rough estimation of the blood flow may be obtained, however, from observation of the ease with which blood can be obtained by a needle prick. Furthermore, even if the methods described hereafter are used for calculating the total amount of plasma needed, observation of the state of the peripheral circulation may give an adequate indication of the necessary rate of administration of plasma.

Method 2 (first aid formula<sup>15</sup>) When laboratory facilities are not available, the dose of plasma may be calculated according to the extent of the body surface involved by the burn. This is estimated by Berkow's

formula<sup>17</sup> and 50 cc of plasma should be given for every per cent of the body surface affected by a deep (blistering) burn. The formula roughly gives the entire amount of plasma that will be necessary, this amount should not be administered all at once but according to the following schedule: one third the first two hours, one third the next four hours and one third the next six hours.

Method 3 (Black's formula<sup>17</sup>) This involves the administration of an amount of plasma in cubic centimeters equal to one thousand times the product of the difference of 5 less 500 divided by the percentage of hemoglobin observed after the burn.

smaller according to the body weight, while, in the rare instances in which the plasma protein is abnormally low, additional amounts should be given according to well established surgical principles.

Two case reports illustrate the use of these methods.

CASE 1—W. K., a man aged 37, suffered flame burns as shown in figure 2, involving 20 per cent of the body surface. The hematocrit reading twelve hours after the burns occurred was 57 despite the transfusion of 500 cc of plasma. At that time the formulas indicated the following doses of plasma:

First aid formula 1,000 cc (50 cc for each of the 20 per cent of the body surface involved)

Black's formula 1,040 cc

Fig. 3 (case 2)—Metabolic studies of severely burned patient

Method 4 (Elkinton's formula<sup>18</sup>) This formula is even more complicated than that of Black and involves as variables the body weight, the plasma protein and the hematocrit reading after the burn.

Method 5 (author's formula<sup>19</sup>) Realizing that the formula of Black and that of Elkinton were somewhat complicated for everyday use, I devised a rule which involves the administration of 100 cc of plasma for every point the hematocrit reading exceeds the normal of 45. For children the dose should be proportionately

Elkinton's formula 1,850 cc

Author's formula 1,200 cc (100 cc for each of the twelve points the hematocrit reading was above 45)

In the second case the agreement was even better. In none of the cases studied were the differences in the results given by the various methods therapeutically significant.

CASE 2—T. W., a youth aged 18, received flame burns involving approximately 48 per cent of the body surface. The subsequent course is shown in figure 3. When the peak hematocrit reading was obtained the formulas indicated the following amounts of plasma to be necessary:

First aid formula 2,400 cc (50 cc for each of the 48 per cent of the body surface involved)

Black's formula 1,910 cc

Elkinton's formula 2,390 cc

Author's formula 2,800 cc (100 cc for each of the 28 points the hematocrit reading was above 45)

16 Berkow S. G. A Method of Estimating the Extensiveness of Lesions (Burns and Scalds) Based on Surface Area Proportions. Arch Surg 8: 138-148 (Jan) 1924

17 Black D. A. K. Treatment of Burn Shock with Plasma and Serum. Brit M J 2: 693 (97) (Nov 23) 1940

18 Elkinton J. R., Wolf W. A. and Lee W. E. Plasma Transfusion in the Treatment of the Fluid Shift in Severe Burns. Ann Surg 11: 150-157 (July) 1940

19 Harkins H. N. The Treatment of Burns with Particular Emphasis on the Management of Burn Shock. Brochure distributed in connection with Scientific Exhibit, Ninety-Second Annual Session of American Medical Association, Cleveland, June 2-6, 1941

At the time of the next hematocrit reading, of 57 (fig 3), the last three formulas (Black's, Elkinton's and mine) gave requirements of 1,030, 1,300 and 1,200 cc of plasma, respectively

From these and similar data it is seen that my simplified formula gives results which agree satisfactorily with those obtained from more complicated equations.

As to recovery of permeability of capillaries subjected to thermal trauma, experimental results of mine<sup>20</sup> and clinical observations of Tenery<sup>21</sup> and others indicate that much of the plasma leakage occurs rapidly. Fifty per cent of such leakage may result during the first hour. This indicates the necessity for prompt treatment. The work of Rhoads, Wolff and Lee<sup>22</sup> indicates that the capillaries may regain their normal permeability more rapidly when the patient is given adrenal cortex extract. Figure 4 demonstrates a method of showing the time of recovery of a normal plasma balance.

CASE 3—B S, a white man aged 21, who weighed 68 Kg, was burned at 3 a m on Feb 11, 1941, when his oil soaked clothes caught on fire after an oil stove exploded (figs 5, 6 and 7). Resoreinol and tannic acid jelly and sulfaguandine were applied locally. Desoxycorticosterone acetate 2 cc was injected intramuscularly every four hours for five days, and one dose of 1,500 units of tetanus antitoxin was administered. By transfusion 2,200 cc of blood plasma was given in the first thirty-six hours. The patient was never in shock, but he died April 7, fifty-five days after being burned.

The plasma balance line of this patient occupies the middle of figure 4, while the hematocrit readings are graphed at the top and the actual amount of plasma injected is charted at the bottom. The middle line, showing the plasma balance, represents the plasma change per hour in cubic centimeters. This is listed as a loss (negative values) or a gain (positive values) in the amount of plasma in the blood stream calculated by Elkinton's formula<sup>18</sup>. The first point on this line represents an average plasma loss from the blood stream per hour of 210 cc. This was six hours after the burn and was calculated from the results shown in table 1.

Fig 4 (case 3)—Course of burn and calculations of dose of plasma

The Elkinton formula indicated a deficit of 1,250 cc after six hours, or 210 cc per hour. The second point shows an average plasma loss of 100 cc per hour. This was calculated as follows. The Elkinton formula indicated an added deficit of 510 cc ( $1,760 - 1,250$ ) despite the administration of 300 cc of plasma. This represents a total deficit of  $510 + 300 = 810$  cc over

an eight hour period, or 100 cc an hour. The other points were calculated accordingly and represent the combined deficit plus loss of plasma given.

The progressive decrease in rate of plasma loss with a complete recovery of balance at the end of the third day is of interest. This undoubtedly represents a restitutio in integrum of the capillary permeability to

Fig 5 (case 3)—Burned area according to Berkow's formula (one third of head 2 per cent, one thirty sixth of hands and arms 0.5 per cent, one seventh of anterior portion of trunk 3 per cent, one fourth of posterior portion of trunk 4.5 per cent, both thighs 19 per cent, both legs 14 per cent, total 43 per cent)

proteins. This patient received no adrenal cortex extract, which may account for the slowness of the recovery according to the work of Rhoads, Wolff and Lee<sup>22</sup>.

**Treatment of Toxemia**—Burn toxemia is undoubtedly related to a disturbance of hepatic function, since it is usually accompanied by jaundice and an abnormal response to hepatic function tests (including prothrom-

bin, cephalin-cholesterol and hippuric acid). Furthermore, as first shown by Wilson, Macgregor and Stewart,<sup>22a</sup> the chief consistent postmortem finding in fatal cases of burn toxemia is a severe focal central necrosis of the liver. Since the liver is damaged, the usual methods of protecting this organ are advisable. These include the administration of adequate amounts of dextrose and of protein. The use of plasma is helpful in the treatment of toxemia as well as in the treatment of shock.

**Treatment of Sepsis**—Careful and aseptic local treatment is the best prophylactic means of controlling burn sepsis, while use of the sulfonamides offers considerable promise in the therapeutic control of this complication.

#### LOCAL TREATMENT OF THE BURNED AREA

Local treatment should at all times be carefully coordinated with the general management of the burned patient. This principle is one of the most important in all burn therapy.

**Means of Treatment**—At the present time there are many means of local treatment, all of which have their enthusiastic advocates. The very multiplicity of the preparations shown in table 3 indicates the lack of agreement on this aspect of the subject. Without attempting to render a didactic decision as to their relative merits, several of these means of treatment will be listed hereafter:

1. **Tannic Acid Spray**—This is the parent technique of all the coagulating modes of treating burns. Introduced by Davidson,<sup>22</sup> it led rapidly to a number of variants including application of tannic acid jelly, tannic acid baths, use of tannic acid and silver nitrate, and application of gentian violet and silver nitrate. The use of the sulfonamide drugs in combination with tannic

acid has considerable promise. Tanning agents have the advantage of rapid action with minimum subsequent nursing care. The importance of repeated painting of the edges of the tanned eschar with gentian violet or brilliant green has been emphasized by war surgeons in Great Britain.

**2 Tannic Acid and Silver Nitrate** This combination which was introduced by Bettman<sup>23</sup> has the merit of even more rapid action than tannic acid alone. The burned surface is covered with a protective coating within minutes instead of hours and this is of considerable importance in wartime.

**3 Gentian Violet** Introduced by Aldrich<sup>24</sup> this dye has found considerable use in the treatment of burns. It promises more antiseptic action than does tannic acid and gives a more pliable eschar. It is slow in action, however, and soils bed linen.

**4 Triple Dye** The mixture of crystal violet, acriflavine and brilliant green in essentially 1 per cent concentration each was introduced by Aldrich<sup>25</sup> to combine action against gram-negative as well as gram-positive organisms.

**5 Gentian Violet and Silver Nitrate** First used by Branch,<sup>26</sup> this combination is similar to tannic acid and silver nitrate.

**6 Sulfadiazine Spray** Pickrell<sup>27</sup> used 35 per cent sulfadiazine in triethanolamine solution as a spray. This is applied every hour the first day, every two hours the second day, every three hours the third day and every four hours the fourth day.

Fig 6 (case 3)—Burns soon after admission. Hairs are still in place on the right shin in spite of the fact that this is a deep third degree burn.

**7 Sulfonamide Ointments** These may be used alone or in combination with cod liver oil. They are especially useful for burns of the face, hands, feet and perineum.

**8 Bunyan (Oiled Silk) Envelops** These are especially popular in Great Britain but were not entirely original with Bunyan<sup>28</sup>. Their main applicability is for deep burns of the hand, but various shaped envelops with inlet and outlet vents for through and through irrigation may be fitted to other parts of the body.

Other means of treatment may be equally useful but no assessment of their relative merits will be made here.

**Principles of Closure of the Wound**—One of the most important of all principles in the care of deep burns is that of closure of the wound. Just as no one

would think of leaving the abdomen wide open after an intra-abdominal exploration so any one who assumes the responsibility of a deep burn should see to it that the surface is epithelized as soon as possible. Skin grafting is usually done too little and too late. The methods of grafting have been reviewed elsewhere<sup>29</sup> but the importance of the operation must be reemphasized here. When a granulating surface resulting from a burn exists, every effort should be made to get the local area and the condition of the patient as a whole ready for skin grafting as soon as possible.

Fig 7 (case 3)—Appearance of burns after complete tanning.

#### WAR BURNS

Thermal injuries received during the present conflict are distinguished to a large extent by their depth and localization to the hands and face.

The depth of the burns makes coagulative methods of therapy less beneficial than in the case of shallower injuries.

Just as one would hesitate more to close a deep puncture wound than a shallow laceration so the tendency is toward use of an ointment or a saline solution dressing for deep war burns. This is especially true since the hands and face are considered unfavorable sites for tanning.

Mason<sup>30</sup> advocated a pressure dressing over petrolatum gauze for treating hand burns. In Great Britain many writers have opposed the use of tanning agents on

Fig 8—Dupuytren's classification of burns according to depth (from Harkins<sup>31</sup>).

the hands and face, including Mowlem<sup>31</sup>, Wakeley,<sup>32</sup> the Heggies<sup>33</sup> and Robson and Wallace<sup>34</sup>. A few desultory reports have continued to recommend tannic

acid for all regions of the body (e g, Cohen<sup>35</sup>), but the general tendency is in the opposite direction

From the practical standpoint it is useless to try to decide too carefully during its early stages as to the depth of a burn. Burns are divided into three degrees according to depth by Boyer's classification (redness,

to Wallace,<sup>37</sup> such burns should be immersed and the phosphorus particles picked out under water. Successive washings with mild sodium bicarbonate, 1 per cent copper sulfate and boric acid solutions should be followed by a saline solution dressing. Oils and greases should be avoided.

In naval engagements, burned patients are especially apt to be covered with grease or oil. The coating may be so difficult to remove that tanning therapy is indicated. If the decision is made to remove the oil, this should be done with benzene, ether, soap, turkey red oil or Fantus's ether soap.<sup>38</sup> The objection to the use of ether or benzene is that these substances cannot safely be carried in large quantities aboard ship.

blistering and granulation producing) and into six degrees by Dupuytren's classification (fig 8)

A type of burn especially prevalent in the present war is the so-called aviator's burn. When an explosion occurs in an airplane, the aviator throws up his hands to protect his face, burning the backs of the hands as well as the face. Such burns are often deep and involve a considerable amount of convalescent plastic care, especially for the fingers and the eyelids. In Great Britain burns of the hands of this type are often treated with Bunyan envelops. Wakeley<sup>36</sup> stated in this regard: "The best preliminary dressing for burns of the hand is a saline bath. The hands should be immersed in a bath twice a day and the patient encouraged to move his fingers in the bath. A saline pack is applied after the bath and this is kept moist and allowed to fall off in the next saline bath." Use of the

sulfonamides, especially locally, has a distinct applicability in the cases of such burns.

Phosphorus burns are especially apt to occur from incendiary bombs and self-igniting phosphorus grenades. Because small particles tend to become embedded under the skin, these injuries are apt to be deep. According

to Wallace,<sup>37</sup> such burns should be immersed and the phosphorus particles picked out under water. Successive washings with mild sodium bicarbonate, 1 per cent copper sulfate and boric acid solutions should be followed by a saline solution dressing. Oils and greases should be avoided.

In naval engagements, burned patients are especially apt to be covered with grease or oil. The coating may be so difficult to remove that tanning therapy is indicated. If the decision is made to remove the oil, this should be done with benzene, ether, soap, turkey red oil or Fantus's ether soap.<sup>38</sup> The objection to the use of ether or benzene is that these substances cannot safely be carried in large quantities aboard ship.

The study of burns is of especial importance in the

THE PITUITARY TYPE OF  
MYXEDEMA

## FURTHER OBSERVATIONS

JACOB LERMAN, MD

BOSTON  
AND

H D STEBBINS, MD

MARBLEHEAD, MASS

Last year Means, Hertz and Lerman<sup>1</sup> described their sequence of experiences leading to the recognition of the pituitary type of myxedema. First it was noted that patients with Addison's disease have acute adrenocortical failure when thyroid is administered to them, second, that some patients with apparent myxedema do not respond well to thyroid. One such patient actually went into coma and died. At autopsy—the endocrine organs presented the characteristic changes of Simmonds' disease, namely, atrophy of the pituitary, thyroid, parathyroids, adrenals and ovaries. This knowledge permitted them to establish the proper diagnosis and institute proper treatment when the next patient with apparent myxedema went into coma on administration of active thyroid material.

Our purpose in the present report is to describe in more detail the metabolic studies made on this patient and to describe the pathologic manifestations in another case recognized before death.

## REPORT OF CASES

The history of patient 1 was given in full in a previous publication.<sup>1</sup> For the convenience of the reader of the present publication the important points will be restated.

**CASE 1**—Mrs S, aged 30, was recognized on sight as suffering from myxedema. She was admitted to the hospital March 1, 1939 in a state of semistupor which followed the onset of an infection of the upper respiratory tract. She complained of vomiting and abdominal cramps. With no special treatment but forcing of foods and fluids she improved rapidly in twenty-four hours. Her sister related that for several years she had had similar episodes, usually following infections of the upper respiratory tract, and that in a few days she would come out of them. Seven years before entry, following the birth of her second child, she complained of fatigue, headaches, puffiness of the eyes and ankles, faintness aversion to cold and spells of dyspnea. These symptoms had persisted and, in addition she had gained 15 pounds (68 Kg). Amenorrhea and loss of libido had ensued after the last pregnancy without the accompaniment of hot flashes. It was later discovered that after this pregnancy she had had a severe postpartum hemorrhage with inversion of the uterus, requiring laparotomy and two transfusions.

Physical examination presented an appearance characteristic of myxedema. There were, however, several atypical features namely atrophic breasts, sparse pubic and axillary hair, absence of body hair atrophic vaginal mucosa, infantile uterus and low blood pressure (94 systolic and 72 diastolic)—one expects normal or high blood pressure in ordinary myxedema. The laboratory studies also were atypical in some respects but typical in others. The hypochromic anemia, the gastric anacidity, the low basal metabolic rate—varying from minus 40 to minus 52—the low voltage and flat T waves in the electrocardiogram and slow alpha rhythm in the electroencephalogram

were all characteristic of myxedema, whereas the blood cholesterol of 112 to 120 mg per hundred cubic centimeters and serum protein of 4.8 to 6.6 Gm per hundred cubic centimeters were unusual for myxedema.

When the patient was placed on active thyroid preparation her metabolism rose to minus 18 in six days, but the patient did not respond in the expected manner. Anorexia, nausea, vomiting and abdominal pains developed, she became drowsy and responded slowly and the blood pressure remained low. The blood sugar was low, 42 mg per hundred cubic centimeters, and the total base in the serum was 134 milliequivalents per liter, an extremely low value.

At this point it became apparent that the diagnosis of myxedema was in error—that she was probably suffering from anterior pituitary hypofunction and that thyroid therapy had thrown her into a state of adrenocortical insufficiency plus hypoglycemia. Consequently thyroid medication was stopped and intravenous dextrose in saline solution given immediately. On this she improved rapidly and in a few days was well enough to permit extensive studies of her total endocrine picture.

The insulin tolerance test, as indicated in figure 1, showed a slightly faster fall than normal, very little recovery at the

Fig 1 (case 1)—The insulin tolerance tests on Mrs S compared with the composites of tests on normal persons and on patients with primary thyroid myxedema.

end of two hours and only a slight response to epinephrine. The curve is calculated on the basis of the percentage of fasting level. The absolute blood sugar values were also lower than those of normal or myxedematous persons. Such a curve is characteristic of patients with hypofunction of the anterior lobe.<sup>2</sup> It indicates insulin sensitivity and failure of the diabetogenic hormone of the pituitary to restore the blood sugar level to normal. A second test done two months later, showed a similar response to insulin and also failure of the blood sugar to respond to epinephrine. This resulted in a second attack of coma again relieved by dextrose and saline solution intravenously.

The test for follicle stimulating substance in the urine was negative indicating that her amenorrhea was due not to primary ovarian failure but rather to pituitary failure.

The test for 17 ketosteroids in the urine showed an amount less than 0.5 mg in twenty-four hours. This is equal to the blank. Since this test is an index of activity of the gonads and adrenal cortex in the male and of the adrenal cortex only in the female such a result indicates adrenocortical hypofunction either due to primary adrenal disease or secondary to hypofunction of the anterior pituitary.

Study of the salt metabolism revealed abnormal levels in the blood and abnormal amounts excreted. As shown in the accompanying table, the blood sodium and chloride were low and the loss of chloride in the test described by Wilder<sup>4</sup> was high. Such results are characteristic of adrenocortical hypo-

for the body by diminishing the excretion of salt. In addition, she excreted 44 mg of 17 ketosteroids in twenty-four hours on the day after the last injection of extract of pregnant mare's serum.

Following another attack of coma on May 3, she was put on a high salt diet with 6 Gm of salt added. As a result, the sodium and chloride levels of the blood rose further, as indicated in the table. The next effort was to determine whether any of the commercial pituitary preparations could substitute for this patient's deficiency. She received eighteen doses of Squibb's anterior pituitary extract, 2 cc daily intramuscularly from May 8 to May 25, in addition to the high salt intake. The only definite effect obtained from this was gonadotropin, as indicated by changes in the vaginal mucosa to normal. The metabolism was not affected, fluctuating between minus 30 and minus 40. The already normal levels of sodium and chloride in the blood were maintained. Beginning June 1, she received a preparation intramuscularly of anterior pituitary thyrotropic substance made by Parke, Davis & Co, 1 cc daily for seven days and 2 cc daily for seven days. No definite change in clinical appearance or in metabolism was observed.

She was discharged on June 19, 1939 on a regimen which consisted of a high salt diet, 4 Gm of extra salt and intramuscular injections of extract of pregnant mare's serum 20 units three times a week for two weeks, alternating with two week periods without injections. This was carried out for

Fig 2 (case 2)—Low power view of the pituitary of Mrs. H. The anterior pituitary is almost completely replaced by fibrous tissue. All that remains of the anterior pituitary (a) is shown in the photomicrograph. The posterior lobe (p) is normal.

function and agree with those reported by Stephens<sup>5</sup> for hypopituitarism.

These tests all confirmed the diagnosis of primary anterior pituitary hypofunction with manifestations of thyroid atrophy predominating. It became clear that any plan of treatment must take into consideration the importance of protecting the adrenal glands. She therefore received daily doses of an extract of pregnant mare's serum (gonadogen<sup>6</sup>) 20 units intramuscularly from April 11 to April 21 (eleven doses). She improved considerably, felt alert and was able to walk around a good deal, and the metabolism fluctuated. There was definite estrogenic effect as indicated by increased folding of the vaginal mucosa, disappearance of atrophy, increase in mucus and a rise in the excretion of estrogens from 16 international units in twenty-four hours before treatment to 30 international units in twenty-four hours after treatment. The content of sodium and chloride in the blood increased and the Wilder test indicated a more normal type of chloride excretion (table). Thus it would seem that the estrogenic material resulting from gonadotropic stimulation of the ovary was able to spare salt

Fig 3 (case 2)—High power view of a portion of the anterior pituitary shown in boxed section in figure 2. The surviving anterior pituitary cells appear normal.

6 This material was supplied by Dr. E. G. Upjohn of the Upjohn Company.

six months. In the first two months she had normal periods. In the subsequent months she had premenstrual symptoms highly suggestive of periods. Her libido, which had been absent during her illness, returned to her previous normal level shortly after treatment was begun. Her breasts

increased in size, and glandular tissue developed. Her eyebrows regrew, the hair on her scalp increased in amount and the skin became softer. The level of metabolism after treatment averaged 10 per cent higher than the pretreatment level. During this period of treatment she had one severe infection of

gradually raised to  $\frac{3}{4}$  grain (0.05 Gm) daily and has been maintained to date. At various times she has received injections of extract of pregnant mare's serum, 20 units three times a week for two weeks, alternating with a two week period without injections. Her physical condition has been entirely normal, her metabolic rate varies between minus 15 and minus 20. She is active and leads a normal sex life. Although she has not had any more periods, abdominal cramps and breast symptoms always develop ten to fourteen days after a series of injections of the extract of pregnant mare's serum.

No doubt the ideal treatment in this case is to replace all the tropic hormones of the pituitary or to supply all the hormones produced by the glands which are stimulated by the pituitary. In practice, the pituitary extracts have not been satisfactory for human use. The minimal requirements are thyroid and something to protect against adrenal insufficiency. In this case extra salt and gonadotropic substance from pregnant mare's serum have proved adequate.

As indicated in the previous report, the experience with this and similar cases has put us on the alert for myxedema of pituitary origin. Another such case was recently observed and is reported here because post-mortem examination confirmed the diagnosis.

Fig. 4 (case 2)—Low power view of the thyroid showing fibrosis, dense lymphoid tissue and a few scattered thyroid follicles.

the respiratory tract, but unlike the previous infections it did not cause her to go into coma or to have abdominal cramps.

She was readmitted December 26, six weeks after omission of all medication in order that she might be studied further and to reevaluate the effect of gonadotropic substance and of thyroid. Without treatment the blood chemistry was the same as during the previous admission and the excretion of chlorides was high. After receiving 20 units of extract of pregnant mare's serum daily from Jan. 22, 1940 to February 5 (fifteen doses), she showed changes similar to the ones observed before. The blood sodium and chloride levels rose (table), but the excretion of chlorides during the Wilder test remained abnormally high. The effect on the endometrium was shown in biopsy specimens by a change from an "inactive endometrium" before treatment to a "proliferative endometrium" after treatment. Unfortunately, it was not possible to determine by biopsy whether or not a secretory phase developed later. The effect on the excretion of 17 ketosteroids in the urine was definite but not large. Two of 3 specimens of urine before treatment contained less than 0.5 mg. of 17 ketosteroids in twenty-four hours, whereas 2 specimens after treatment both contained more than 1 mg. in twenty-four hours.

On February 9 she was started on a high salt diet plus 4 Gm. of added salt and desiccated thyroid,  $\frac{1}{4}$  grain (0.016 Gm) daily. The dose of thyroid was raised to  $\frac{1}{2}$  grain (0.032 Gm) on February 18. On this dosage the basal metabolic rate rose to a level of minus 22 in about two weeks and she lost most of her myxedematous appearance. There was no evidence of adrenal insufficiency. In fact both the blood sodium and the blood chloride reached higher levels (140.8 and 105.7 milliequivalents per liter respectively). The dose of thyroid was

Fig. 5 (case 2)—High power view of the thyroid showing fibrosis, dense lymphoid tissue and a few scattered thyroid follicles.

CASE 2—A woman aged 68 was seen June 15, 1940 because of a fainting spell. Since she presented the clinical appearance of myxedema (subnormal temperature, a slow feeble pulse and in addition low voltage and flat T waves in the electrocardiogram) she was given desiccated thyroid 3 grains (0.2 Gm.)

daily After four days thyroid was stopped because alarming symptoms of weakness, nausea, vomiting and finally coma developed. The woman's companion then added the information that myxedema and amenorrhea had developed after the birth of her first and only child some forty years previously. The delivery had been difficult and complicated by severe hemorrhage. During the ensuing years several physicians had prescribed thyroid, but each time the patient had discarded it after a few days because it did not agree with her, i. e. it produced nausea, vomiting and weakness.

Examination at this time showed that the patient was well developed and well nourished, she was propped up in bed was breathing rapidly and shallowly and was unresponsive. The skin was pale, dry and coarse, the face had the puffy appearance characteristic of myxedema and the tongue was large. There was no pubic, axillary or body hair, and the eyebrows and hair on the scalp were scant. The heart was not enlarged, the sounds were rapid, regular and feeble, the blood pressure varied between 110 and 130 systolic and 90 and 100 diastolic. The lungs were normal except for a few scattered rales, the abdomen was distended and the extremities showed slight pitting edema. The temperature was 99.2 F and she had a slight anemia.

It appeared likely that the patient had the pituitary type of myxedema and that thyroid medication might have been a factor in the production of her comatose state. Since further studies to confirm the diagnosis were not feasible, she was treated with an intravenous infusion of 1,500 cc of 5 per cent dextrose in physiologic solution of sodium chloride. She was already completely digitalized. She made no response, however, and died several hours later.

Postmortem examination<sup>7</sup> revealed that the immediate causes of death were coronary occlusion with recent left ventricular infarction, mural thrombosis of the left ventricle and embolism of the basilar artery. The interesting and unusual conditions were found in the endocrine glands.

The pituitary was deeply sunken in its sella and decidedly atrophic. No definite anterior lobe was distinguishable. As shown in figures 2 and 3, the anterior lobe was almost completely replaced by dense fibrous tissue. Only a few islands of normal appearing epithelial cells were still present. There was no evidence of thrombosis or inflammatory reaction. The posterior lobe appeared normal.

The thyroid was completely atrophic and weighed less than 2 Gm. Microscopic examination (figs 4 and 5) showed that the gland was composed of patchy fibrosis, dense lymphoid tissue and only a rare thyroid follicle. The few follicles seen were small, were lined with cuboidal epithelium and did not contain any colloid.

Fig 6 (case 2)—Low power view of the entire adrenal gland. Note the extreme atrophy. Reduced from a photomicrograph with a magnification of 10 diameters.

The adrenals also were atrophic, as shown in figure 6, and together weighed about 4 Gm, the normal being about 12 Gm. Microscopic sections, however, showed no cellular abnormalities.

The parathyroid glands and the pancreatic islets were normal grossly and microscopically. The ovaries showed complete atrophy and fibrosis—conditions consistent with the patient's age. The only other important abnormalities were generalized arteriosclerosis and terminal bronchopneumonia.

It is not possible to say how much of a role the thyroid medication played in the cause of death. The coronary occlusion by itself was sufficient to cause death. The adrenal insufficiency, which was probably present, may have been a contributing factor. On the other hand, one cannot rule out the possibility that thyroid medication may have initiated coronary occlusion.

\* Patient vomited and in addition did not consume the entire dose.

#### COMMENT

It must be emphasized that not all cases of hypopituitary disease give the appearance of myxedema. Although all the glands are involved, they are not depressed to the same extent in every instance. In one the emphasis may be on myxedema, in another on adrenocortical insufficiency, on hypogonadism or on decreased diabetogenic activity. The recognition of the pituitary type of myxedema has been discussed in the previous report,<sup>1</sup> but is briefly repeated here for emphasis.

The development of amenorrhea earlier than the expected menopause, particularly without the usual menopausal symptoms, suggests anterior pituitary disturbance. Also, the history of postpartum hemorrhage followed by failure to lactate, permanent amenorrhea and loss of libido, as emphasized by Sheehan,<sup>8</sup> is strong evidence for this disease. In the male, loss of libido and impotence have a similar significance.

On physical examination the important findings suggestive of the pituitary type of myxedema are atrophy of the breasts, vaginal mucosa and uterus in women, eunuchoid habitus in men, scant axillary, pubic body hair and persistent hypotension.

The laboratory procedures of importance are those which detect the presence of other endocrine disturbances. The reduction in the levels of blood glucose and chloride and increase in chloride excretion (W)

<sup>7</sup> Dr Benjamin Castleman performed the autopsy on this patient and gave the authors permission to report the results.

<sup>8</sup> Sheehan, H. L. *Simmonds Disease Due to Pituitary Deficiency of the Anterior Pituitary*, Quart J Med 8: 277 (Oct) 1917.

test) indicate adrenocortical insufficiency. The quick drop in blood sugar and its slow recovery following the injection of insulin is evidence of the unopposed action of insulin occasioned by the absence of diabetogenic substance of the pituitary. A negative test for follicle stimulating substance in the urine past the time of the menopause indicates pituitary hypofunction. The absence of 17 ketosteroids in the urine indicates adrenocortical hypofunction of pituitary origin in either sex. These are also absent however in females with Addison's disease. In primary thyroid myxedema the 17 ketosteroids are present but low in amount. The blood cholesterol, usually highly elevated in primary thyroid myxedema, is as a rule low in the pituitary type.

Finally, the response to thyroid may be most important in establishing the diagnosis. The onset of nausea, vomiting, weakness, abdominal pains, collapse and coma after average doses of thyroid is strongly suggestive. Ordinary myxedema seldom fails to make the expected improvement on thyroid, the pituitary variety usually responds unfavorably.

Treatment of myxedema of pituitary origin must be based on the fact that thyroid in such cases, may produce adrenocortical failure and hypoglycemia. Thyroid must therefore be administered with caution. At the same time measures must be taken to protect the adrenals. In case 1 a combination of salt and gonadotropic substance from pregnant mare's serum to stimulate the production of estrin was successful in protecting against adrenocortical failure in spite of the employment of an adequate amount of thyroid. The production of antihormones (antibodies) by similar gonadotropic substances, as reported by Rowlands and Spence,<sup>9</sup> raises theoretical objections to the continued use of such hormones. Thus far this extract of pregnant mare's serum has not failed to produce an adequate response in this patient.

#### SUMMARY

In a previously published case of myxedema due to anterior pituitary hypofunction the diagnosis was confirmed by laboratory procedures which indicated gonadal and adrenocortical hypofunction and absence of gonadotropic and diabetogenic substances of the pituitary. Treatment designed to raise the metabolism with thyroid and at the same time to protect against adrenocortical "crises" was successful. In the second case reported here the diagnosis was confirmed post mortem by anatomic evidence of atrophy of the pituitary, thyroid and adrenal glands.

**The Eternal Search for Values**—To live intelligently requires conscious effort on the part of the individual. He must ever seek to develop those abilities which nature gave him. He must profit by his own experiences and those of other men living and dead by constantly seeking meanings and wider implications. He is growing in wisdom. He must participate in life to the full. He must join the eternal search for more satisfying values. Long ago John Bunyan said that these paths lead to the Delectable Mountain where peace and satisfaction were to be had. We may not know that at the end there is the Delectable Mountain but we do know that those who tread this way of life do send back reports to us that the journey was one of adventure, interest, joy and satisfaction.—Oppenheimer, J. J. Some Characteristics of the Scholarly Ideal in Everyday Student Life. *Ism. Im Coll. Bull.* 26: 222 (May) 1940.

## CIRCUMSCRIBED INTRATHORACIC NEOPLASMS

JOHN ALEXANDER, M.D.

ANN ARBOR, MICH.

There is a prevailing impression among many physicians that most circumscribed intrathoracic neoplasms are extrapulmonary and benign, and that their prompt removal is not important. The basis for this impression is in part the fact that a considerable number of small circumscribed neoplasms at first cause few or no troublesome symptoms and also that such tumors may, for a period of months, remain apparently stationary with regard to growth. The truth is that a majority of circumscribed intrathoracic neoplasms arise within the lung (almost all of them being malignant),

Fig. 1—Approximately similar appearance of neoplasms in four different patients. A lymphoblastoma. B neurofibroma extending far into spinal canal through intervertebral foramen. C fibrosarcoma of mediastinum. D bronchogenic carcinoma of upper lobe invisible by bronchoscopy.

many of those that arise outside the lung are malignant and, therefore, the prompt removal of any circumscribed neoplasm which cannot be proved benign is of vital importance.

The preoperative demonstration of the exact nature of primary intrathoracic neoplasms is usually impossible unless a specimen of tissue can be obtained for microscopic examination by bronchoscopy, esophagoscopy, needle aspiration or from a metastatically involved lymph node in the neck, axilla or elsewhere. About 70 per cent of the carcinomas of the lung arise in the large bronchi from which bronchoscopic biopsy specimens may be obtained. The roentgenologic shadows in the cases of this group are usually not well circumscribed, but the shadows in the 30 per cent or the cases in which no lesion can be seen bronchoscopically and in which the tumor is in the lung at a distance

From the Department of Surgery, University of Michigan Medical School.

Read in the symposium on Diseases of the Chest at the fifteenth postgraduate celebration of the University of Chicago, Sept. 2, 1941.

from the large bronchi are usually well circumscribed. Although the infiltration produced by carcinoma of the esophagus (from which biopsy material is almost always obtainable during esophagoscopy) is generally circumscribed, the external outline of the tumor mass is rarely demonstrable roentgenologically. For reasons that will not be considered here, needle aspiration of intrathoracic tumors for the obtaining of biopsy material is, in my opinion, inadvisable except when a patient's general condition is so poor that the risk of surgery should not be accepted unless the tumor was known to be malignant.

The position of neoplasms within the chest helps to suggest their nature, but mistaken diagnoses, when based on this criterion, are so frequent that the physician must guard against managing his patients on a presumptive diagnosis so made.

The differentiation between intrapulmonary and extrapulmonary tumors is important and sometimes difficult. When a tumor is visible bronchoscopically it almost certainly arose within the lung. When a tumor

monary tumors that are loosely attached to the thoracic wall move synchronously with the lung.

While circumscribed extrapulmonary neoplasms in the costovertebral region are usually neurofibromas, and those in the anterior half of the chest are usually teratomas, there are too many exceptions to this "rule" to justify reliance on it. The illustrations for this article have been chosen to demonstrate that approximately similar roentgenologic shadows may represent diverse types of benign and malignant neoplasms.

Although an exact pathologic diagnosis is of interest, it is of relatively little clinical importance. What is of paramount importance is whether a neoplasm is benign or malignant and, if malignant, whether it is still completely removable. I<sup>1</sup> have invited attention to the fact that a preoperative determination of benignancy or malignancy can only rarely be made in those many neoplasms from which a biopsy cannot be safely carried out or which have not shown a response to high voltage roentgentherapy that is typical of lymphoblastoma or which have not shown evidence of metastasis. Since

Fig. 2—A, benign but very cellular papilliferous teratoid bronchial adenoma lying outside of lung but attached to it; B, neurofibroma with extension into intervertebral foramen; C, bronchogenic carcinoma in lingular portion of upper lobe, invisible by bronchoscopy.

is seen by posteroanterior and lateral or oblique roentgenograms to lie everywhere within the limits of the cortex of the lung it should obviously be considered as intrapulmonary, although an interlobar origin is possible. Large tumors may so completely replace or displace the adjacent parts of the lung that it is roentgenographically impossible to decide whether they arose within the lung and expanded to the costal, diaphragmatic or mediastinal wall of the hemithorax or whether they arose within one of the thoracic walls and displaced the adjacent lung. If a preoperative determination of an intrapulmonary or extrapulmonary site of the tumor should be important, an induced pneumothorax may be used to show, in the absence of extensive pleural adhesions, whether or not the tumor lies within the lung. If a tumor in the lower part of the chest, but not in continuity with the diaphragm, descends with the lung during inspiration, the tumor is likely to be of intrapulmonary rather than extrapulmonary origin. The failure of a tumor to descend during inspiration does not, however, exclude an intrapulmonary origin, since pleural adhesions or malignant invasion of the thoracic wall may so fix that part of the lung containing such a tumor that it will not move appreciably during respiration. Occasionally, extrapul-

monary intrathoracic neoplasms rather frequently undergo malignant degeneration and since those that remain benign tend to cause progressive disability and dangerous complications as they increase in size the patients' safety requires that all presumably removable neoplasms should be promptly operated on whether or not a preoperative pathologic diagnosis has been made.

The increasing use of roentgenology of the chest for the detection of tuberculosis in large groups of people and as a routine method of examination of all patients admitted to hospitals, will result in detection of many neoplasms that have produced no thoracic symptoms whatever (fig. 1 B). Since such neoplasms are as potentially dangerous as those that have produced symptoms, and since the medical profession properly pleads to the public to seek examinations that will detect disease in an early, curable state, physicians should insist on the prompt removal of "silent neoplasms."

Emphasis needs to be placed on the erroneous and the prevalent belief among many physicians and roentgenologists that circumscribed intrathoracic neoplasms are usually benign. With rare exception, circumscribed neoplasms within the lung are carcinoma.

1. Alexander, John. Observations on Intrathoracic Neoplasms. *Surg.* 114: 734 (Oct.) 1941.

Since many circumscribed extrapulmonary neoplasms are malignant, a presumptive diagnosis of benignancy obviously cannot be made with safety. I have operated on a number of patients whose histories or periods of preoperative roentgenographic observation suggested that their circumscribed extrapulmonary neoplasms had been benign for months but in whom the pathologic examination of the tumors showed malignancy, which, however, was often of a low degree of activity. I have seen other patients whose apparently benign tumors had been observed for months or even years without troublesome symptoms and with only a slow growth of their tumors, when troublesome symptoms arose and the rate of growth of the tumors increased, the probable malignant degeneration that had then occurred was not recognized until the lesions had become inoperable through metastasis or extensive invasion of surrounding structures.

If failure to remove circumscribed neoplasms promptly because of the mistaken belief that the great majority of such tumors are benign may be considered the most important error made in the management of intrathoracic neoplasms, the routine use of high voltage roentgen therapy is probably the second most important serious error. The only proper use of high voltage roentgen therapy for possibly removable intrathoracic neoplasms is to determine whether a tumor suspected of being a lymphoblastoma is truly one. In other neoplasms the absence of response, with regard to a decrease in the size of the tumor or improvement in symptoms, fails to indicate whether the tumor is benign or malignant, since many malignant tumors do not respond. If a tumor does decrease in size and if the symptoms improve, the tumor has been shown to be probably malignant but at the cost of a loss of a number of weeks of valuable time, during which metastases may occur, making the lesion inoperable. As high voltage roentgen therapy does not completely destroy malignant intrathoracic neoplasms and as the best that can be expected from it is a temporary improvement, and as the frequent practical effect of its use is the loss of the patient's chance of cure by complete surgical removal of the tumor, high voltage roentgen therapy must be strongly condemned except for suspected or proved lymphoblastomas and for palliation in cases of inoperable malignant neoplasms.

Although the differentiation of intrathoracic neoplasms from non-neoplastic lesions that resemble them is of fundamental importance, the scope of this article does not include the extensive discussion that would be necessary to clarify the often difficult differential diagnoses. The following list of circumscribed non-neoplastic lesions will serve to suggest the methods of examination that may be necessary to differentiate them from circumscribed neoplastic lesions: syphilitic and nonsyphilitic aneurysms of the great vessels and heart, diaphragmatic hernia, entration of a part or of the whole of a hemidiaphragm, megaesophagus, substernal goiter, encapsulated empyema, mediastinal and Pott's abscesses, echinococci, congenital, developmental and acquired inflammatory cysts, a solid or abscessed mass of tuberculous hilar or mediastinal lymph nodes, a circumscribed tuberculous or nontuberculous inflammatory mass within the lung, atelectasis of a single pulmonary lobe in which the roentgen shadow is produced entirely by the atelectasis and not in part by an extension of carcinomatous infiltration from a primary bronchogenic carcinoma that may have produced the atelectasis.

## SUMMARY

1 Contrary to the prevailing impression, the majority of circumscribed intrathoracic neoplasms are intrapulmonary and malignant. Many circumscribed extrapulmonary neoplasms are malignant and those that are benign may undergo malignant degeneration or cause disability or serious complications as a result of increase in size.

2 Except for those bronchogenic and esophageal carcinomas that yield endoscopic biopsy material and those neoplasms that have metastasized, a preoperative determination of malignancy or benignancy cannot be made with reasonable accuracy. Needle aspiration biopsy is not advised unless the patient's general condition is so poor that operation would not be performed unless the tumor was known to be malignant.

3 Since delay in the removal of malignant neoplasms may result in their becoming inoperable and since benign neoplasms are potentially dangerous, virtually all presumably removable neoplasms should be promptly operated on, even though they may, at the time, be producing no troublesome symptoms.

4 The only proper use of high voltage roentgen therapy is as a therapeutic test for lymphoblastoma or for palliation in inoperable malignant neoplasms. The use of roentgen therapy for other purposes is useless and, because of the loss of valuable time in those cases that happen to be malignant, dangerous.

## PYELONEPHRITIS

WITH DEATH IN UREMIA

DAVID STANLEY LIKELY, M.D.

JAMES R. LISA, M.D.

AND

CYRIL SOLOMON, M.D.

WELFARE ISLAND, NEW YORK

It is coming to be realized that bacterial infection of the kidneys—pyelonephritis—plays an important role in initiating and continuing pathologic processes which can result in death by uremia and also that many of these cases are first seen by the internist as arteriosclerotic, cardiovascular renal disease and hypertension. A definite etiologic factor is thus injected into a percentage of the large group of diseases classed as degenerative. This places before medicine the theoretical possibility of diagnosing and curing bacterial infection of the kidneys in the early stage. In the late stage it appears to be impossible to change the trend of these pathologic processes.

Longcope and Winkenwerder<sup>1</sup> in 1933 and Longcope<sup>2</sup> in 1937 stressed the destructive effects of pyelonephritis on the functional efficiency of the kidneys. They reported 22 cases in which the age varied from 15 to 58 years and nonobstructive pyelonephritis had been present for periods of five days to seventeen years. They showed that in the beginning there might be typical acute attacks in children or in women in pregnancy. However, when first seen in the late stages the diagnosis was easily missed as 6 of 14 cases were not recognized till autopsy. Costovertebral pain, pus cells in the urine and bacteriuria when present were

<sup>2</sup> Longcope W. T. Chronic Bilateral Pyelonephritis. Ann. Int. Med. 11: 1-9 (July) 1937.

the findings in their series most suggestive of the correct diagnosis. Pyelography frequently confirmed the diagnosis.

Weiss and Parker<sup>3</sup> made a very intensive clinical and microscopic study of 100 cases. They pointed out that only recently has pyelonephritis been separated from chronic glomerulonephritis. While they found scattered cases described in the European literature and certain features noted by urologists, practically no information was available in the Anglo-Saxon literature until Longcope and Winkenweide emphasized its significance in internal medicine. To quote Weiss and Parker, "As long as 'pyelitis' of early childhood was considered by pediatricians as a benign and transient purulent infection of the renal pelvis, it was not suspected that this condition in its chronic stage is related to certain types of toxemia of pregnancy with apparent recovery observed by the obstetrician, to subsequent attacks of pyuria, treated by the urologic surgeons, and to arterial hypertension of progressive severity, developing years later, and associated with impaired concentrating capacity of the kidney with but a trace of albumin and few or no white blood cells in the urine, cared for by the internist. Only when it became sufficiently recognized that 'pyelitis' is uniformly associated with focal or diffuse inflammatory lesions of the parenchyma of the kidney as well as the pelvis was it suspected that acute 'pyelitis' or pyelonephritis bears a direct relation to the functionally insufficient, contracted and irregularly scarred kidneys of chronic pyelonephritis." Weiss and Parker concluded that pyelonephritis was responsible for 15 to 20 per cent of malignant hypertension. The presence of a normal or increased blood pressure depended on the extent of arterial or arteriolar change. Hyperplastic endarteritis, hyperplastic arteriosclerosis and necrotizing arteriolitis were the changes they encountered. They concluded from the histologic evidence that the arteriolitis was directly caused by bacterial infection. The vascular changes were most noticeable in the renal scars, less so in the rest of the kidney. Furthermore, the vascular changes were confined to the kidney and were not generalized as in "primary" malignant hypertension.

The present communication adds further support for the role pyelonephritis plays in the causation of loss of kidney function and uremia. Our data were obtained from the study of 22 cases of nonobstructive pyelonephritis. They were chosen from 93 cases of uremia that came to autopsy between Jan 1, 1928 and Dec 1, 1941. In this group of 93 cases the main renal pathologic condition was pyelonephritis, including both obstructive and nonobstructive in 32 cases, or 30 per cent. These patients were all admitted to the medical wards. In only 5 was pyelonephritis recognized clinically. In the remainder it was discovered at the autopsy table. The clinical diagnosis was based on a blood nonprotein nitrogen level of not less than 90 mg per hundred cubic centimeters and death in coma. The criteria for the pathologic diagnosis of pyelonephritis used in this communication were essentially the same as those laid down by Weiss and Parker. The kidneys tended to be coarsely scarred, the capsules somewhat adherent, the cut surface showed distortion of cortex and medulla, with blunting of the calices and

dilatation of the pelvis, and in the very acute stages yellow streaks in the medulla extending up into the cortex, sometimes with small abscess formation. Histologically the most pronounced feature was the extensive disorganization, primarily interstitial in nature, with compression of the tubules and a mixed cell inflammatory reaction. The tubules contained pus or hyaline casts, depending on the stage and the activity of the process. The vascular changes were more pronounced in the areas of inflammatory reaction. The glomeruli tended to be unusually well preserved with a comparatively small number hyalinized. In the cases in which death occurred in uremia the lesions of acute glomerulitis were extensive, as pointed out in a previous study.<sup>4</sup> The inflammatory reaction in the pelvis was usually severe and of the same character as that found in the parenchyma.

The age range in the 22 cases was from 16 to 71 years, with an average age of 47.9 years. Each decade was evenly represented excepting in 1 case between 10 and 19 years and 5 cases between 60 and 69. In 2 the age was over 70. Fifteen patients were male and 7 female, contrary to Longcope's finding of a preponderance in females. Seventeen were white and five Negro.

There was a wide range of chief complaints. Abdominal pain, the most common complaint, was present eight times. It was largely epigastric and not associated with food intake. Lumbar or back pain did not appear as a chief complaint. Dysuria appeared only once in a list of forty-five complaints. Dyspnea seven times, edema six, nausea and vomiting five were the other frequent symptoms with the following occurring only once or twice: paralysis of the leg, weakness, diarrhea, tarry stool, purpura, trembling, pain in the chest pain in the joints, precordial pain, anorexia, cough, epistaxis and generalized itching.

The clinical course in 12 cases was largely cardiac alone or cardiac associated with neurologic, ophthalmologic or gastrointestinal elements. All these patients had hypertension. In the 10 other cases the principal picture of the course was ophthalmologic, intestinal obstruction, pulmonary and neurologic, upper respiratory and recurrent cutaneous disorder, gastrointestinal, arthritic, hepatic and neurologic. All the cases presented renal features for a varying length of time before death. In all cases some kidney diagnosis was made, in most not until the renal element was obvious.

The blood Wassermann reaction was positive in 2, there was a history of syphilis in 2, and 18 were negative. The blood pressure was normal in 8, moderately elevated in 6 and highly elevated in 8. The average blood pressure was 175 systolic and 107 diastolic.

The urine showed the following: The specific gravity was fixed in 7, there was a loss of concentration in 1, slight fixation in 6 and considerable reduction in 1. There was no albumin in 1 case, it was 1 plus in 4 cases, 2 plus in 4 cases, 3 plus in 7 cases and 4 plus in 1 case. There were no erythrocytes in 1 case, there were 1 plus in 5 cases, 2 plus in 4 cases, 3 plus in 3 cases and 4 plus in 2 cases. Pus cells were absent in 1 case, 1 plus in 8 cases, 2 plus in 2 cases, 3 plus in 4 cases and 4 plus in 6 cases. All showed sharp reduction of phenolsulfonphthalein excretion when the

<sup>3</sup> Weiss, Somer, and Parker, Fred, Jr. *Pyelonephritis*, *Medicine* 18: 221 (Sept.) 1939.

<sup>4</sup> Lisa, J. R., Solomon and Gordon, F. J. *Ureteral Pathologic Study*, *International Clin* 3: 88, 1941.

was done. Morning specimens were not as satisfactory as later specimens for leukocytes and clumps. All urines showed some pathologic elements in some specimens at one time or another. Some showed leukocytes without erythrocytes and others the opposite. Almost all tests showed white blood cells if repeated often enough.

Blood counts were done in 15 of the 22 cases and showed secondary anemia in all but 1 case. The white count ranged from 3,400 to 17,200 cells, the latter in an acute exacerbation of pyelonephritis.

The following three cases are illustrative of this group.

CASE 1—R. C., a white man aged 48, admitted to the service of Dr. Donaldson with the complaint of pain in the joints of the hands, shoulder and knees, for three months, gave no urinary or cardiac history. He had been treated for syphilis. The fundi were normal. The heart was slightly enlarged. X-ray examination revealed no bony joint abnormality. The blood pressure ranged from 132 systolic and 80 diastolic to 160 systolic and 150 diastolic. The urine showed fixation 3 plus albumin, an occasional white blood cell and no red blood cells. The nonprotein nitrogen rose to 225 mg per hundred cubic centimeters. The blood showed a secondary anemia and normal white and differential count. Cystoscopy revealed a mild cystitis and an appearance time of phenolsulfonphthalein of seven minutes on each side. The temperature was normal with a disproportionally elevated pulse rate. The patient gradually became lethargic, had several nosebleeds, became stuporous, went into a coma and died.

The clinical impression was rheumatoid arthritis and later chronic glomerulonephritis with uremia.

The right kidney weighed 170 Gm, the left kidney 130 Gm. The left kidney was more profoundly affected than the right. The kidneys were irregular and nodular; the capsules were adherent and the external surface showed numerous telangiectases. On cut surface the markings were indistinct, the corticomedullary boundary line was obscured and there were numerous yellow streaks throughout the medulla and cortex. The pelvis was dilated and the mucosae had numerous petechial hemorrhages, the contents were purulent.

Histologically there were numerous areas in the cortex and medulla of interstitial lymphoid, plasma and polymorphonuclear infiltration with local fibrosis. The small arteries within the scars were moderately sclerotic. The glomeruli were fairly well preserved, and all showed moderate to severe endothelial hyperplasia with occlusion of the capillary bed. Many of the tubules, particularly of the collecting elements in the cortex and medulla, were filled with pus casts, a few having colloid casts. The pelvis was moderately infiltrated with lymphoid and plasma cells.

CASE 2—A. LaM., a white man aged 58, admitted to the medical service of Dr. Donaldson with complaints of swelling of the abdomen and ankles and pain in the chest for one month's duration, had had ankle edema and ascites for one year, more pronounced the month before admission, dyspnea on exertion and precordial pain for one year. Physical examination revealed edema and sclerotic peripheral vessels. The heart was enlarged to the left and down; a rough mitral systole and soft aortic systolic murmur were heard. The second aortic sound was definitely accentuated. The blood pressure was 264 systolic and 160 diastolic. The liver was enlarged and ascites was present. An electrocardiogram and X-ray examination revealed disease of the ventricular muscle and evidence of pulmonary congestion respectively. Laboratory studies revealed a negative Wassermann reaction and secondary anemia with normal white count and differential. On admission the nonprotein nitrogen was 34, which rose to 129 in one month. Phenolsulfonphthalein clearance was 30 per cent in three hours and the urine showed a fixed specific gravity 3 plus albumin, 4 plus red blood cells and an occasional white

blood cell. The temperature and pulse rate remained elevated throughout the course. The patient suffered from pain in the right upper quadrant, went into coma and died.

The clinical impression was hypertensive cardiovascular disease with uremia and bronchopneumonia.

This case illustrated the almost wholly cardiac type until the mode of death in uremia revealed the true pathologic condition.

The right and left kidneys weighed 175 and 150 Gm respectively. They were coarsely scarred. The capsules were thickened and adherent, and on section there were numerous small petechial hemorrhages and yellow streaks throughout the medulla and cortex. The calices were dilated, the pelvis was thickened and granular. A frankly purulent urine was present on each side.

Histologically the changes were largely acute, with extensive purulent infiltration of the interstitial tissue both in the cortex and in the medulla with some foci of lymphoid and plasma cells. The tubules contained numerous pus casts. The glomeruli were large and plump and had extensive acute changes. The vessels had sclerotic changes throughout all radicles.

CASE 3—E. V., a Negro aged 29, admitted with complaints of nausea and vomiting and pain in the right upper quadrant for four months and epistaxis three times in two months, had had smallpox at 17 and pneumonia at 20. The pain in the abdomen was usually epigastric, did not radiate and had no relationship to meals. There had been constipation for five months previous to admission. The weight loss had been 28 pounds (13 Kg) in four months. The blood pressure was 180 systolic and 130 diastolic. The heart was enlarged. The urine showed fixed specific gravity laterally, 3 plus albumin, clumped white blood cells and urea nitrogen which rose to 219 mg per hundred cubic centimeters. The blood count showed severe secondary anemia and 14,000 white blood cells with 91 per cent polymorphonuclears. The Wassermann reaction was negative. The fundi were normal early and showed hemorrhage and exudation later. Cystoscopy showed non-hemolytic streptococci on urine culture from both ureters.

The clinical impression was nephrosclerosis with uremia, peptic ulcer.

The kidneys weighed 125 Gm each and were coarsely nodular. The capsules were adherent, more at the pelvis than over the cortex, and were studded with small yellow and gray nodules. The cut surfaces showed irregular width of the cortex, blunting of the calices and yellow streaks throughout the medulla and cortex. The pelvis and ureters contained thick purulent urine.

On microscopic examination the kidney showed extraordinary disorganization and interstitial fibrosis with a mixed cell infiltration, frequently purulent. The tubules of the cortex and the medulla contained both hyaline and pus casts. The glomeruli had all stages of acute glomerulitis, only a few were scarred and hyaline. The vessels showed profound sclerosis, many with hyaline and fibrin thrombi. The pelvis had a dense lymphoid plasma and polymorphonuclear infiltration.

#### COMMENT

The foregoing data show the meagerness of the signs and symptoms which clearly point to the diagnosis of pyelonephritis when seen in the late stage. In the acute stage the signs are more diagnostic. Every pediatrician and obstetrician is acutely aware of "pyelitis." The direct connection between acute "pyelitis" of childhood, pregnancy and adult life, whether ascending or hematogenous in nature and chronic pyelonephritis appears to be established. Symptomless pyuria and bacteriuria, especially if preceded by acute attacks with symptoms, must assume a position of large importance in medical consciousness. It is in this blind period of symptomless pyuria with vague nonspecific upset and chronic anemia that it is difficult for the physician to convince either himself or his patient that he is

dealing with an infection which frequently goes on to kidney destruction

Our data confirm previous writers in showing that in a large proportion of cases in which death occurs in uremia the essential cause is bacterial infection of the kidneys. This fact supplies a specific etiologic factor for pathologic processes followed by renal death which previously had been attributed to degenerative cardiovascular disease or to primary nonbacterial inflammatory disease of the parenchyma of the kidneys. It presents to medicine a challenge as, theoretically at least, it is possible to diagnose and cure these patients at an early stage of their illness.

#### CONCLUSION

1 In 22 cases of nonobstructive pyelonephritis, death occurred in uremia

2 They are chosen from 93 cases of uremia coming to autopsy of which 32 were cases of pyelonephritis both obstructive and nonobstructive

3 Most of these cases were instances of degenerative cardiovascular renal disease

4 The series illustrates the importance of long standing pyelonephritis as the basic pathologic condition in a large proportion of the mass of hospital cases usually grouped as degenerative diseases

5 There is presented to medicine a definite challenge for early diagnosis and proper therapy of pyelonephritis to prevent the development of irreversible changes

### THE NAUSEA AND VOMITING FOLLOWING ADMINISTRATION OF DIETHYLSTILBESTROL

J WILLIAM FINCH, M.D.  
HOBART, OKLA

My purpose in this paper is twofold. First, a definite relation is shown to exist between the nausea and vomiting of early pregnancy and the nausea and vomiting which frequently follows the administration of diethylstilbestrol. Second, a method is described by which diethylstilbestrol may be administered with elimination of side effects in those patients who do not tolerate the drug.

#### RELATION OF NAUSEA OF PREGNANCY TO NAUSEA FOLLOWING DIETHYLSTILBESTROL

The clinical material used for this report consists of 95 patients given diethylstilbestrol for periods ranging from three months to two years. Diagnoses include the menopause (natural, surgical and irradiation), hypo-ovarianism, dysmenorrhea, vulvovaginitis of young girls, senile vaginitis, inhibition of lactation (postpartum), menometrorrhagia and 9 cases of benign prostatic hypertrophy.

As the investigation progressed it was observed repeatedly that patients who previously had experienced nausea and vomiting in excessive degrees during pregnancy also had nausea and vomiting following administration of diethylstilbestrol. The intolerance to diethylstilbestrol was in almost every case directly proportional to the severity of the nausea and vomiting of

previous pregnancies. It was noted also that patients in describing their nausea from the drug stated "I felt just as if I were pregnant again. It was the same kind of nausea."

Following this observation, diethylstilbestrol in 1 mg enteric coated tablets once daily at bedtime was administered to 10 patients who had had severe nausea and vomiting of pregnancy, purposely to see if they were sensitive to the drug. No patient was forewarned of any likely side effect. In every case, definite nausea, accompanied by vomiting in 60 per cent of the cases, was produced following administration of one to three doses. Further administration of the drug caused sufficient side effects in each case to prove beyond doubt that it was the diethylstilbestrol causing the symptoms.

A summary of cases treated was then made, with these findings:

Thirty-three women varying in age from 29 to 56 and in parity from one to four had experienced severe nausea and vomiting with each pregnancy. Each of these women had been started on a 1 mg enteric coated tablet of diethylstilbestrol daily. Thirty-two patients of this group (96.9 per cent) had nausea, vomiting, abdominal pains and/or migraine sufficiently severe to make withdrawal of the drug desirable. One patient had no side effects and continued with the same dosage. Two patients were unable to tolerate as little as 0.15 mg of the drug, this small dose causing a hyperemesis for several hours. Side effects began, on the average, about six hours after administration of each dose and continued for three to eight hours.

A control series of 20 women who varied in age from 25 to 56 years and in parity from one to ten had had no nausea whatever with any pregnancy. These women were given doses of from 3 to 8 mg of diethylstilbestrol by mouth each day, and in 19 cases (95 per cent) there was not the slightest side effect from the drug. One woman tolerated 3 mg daily without side effect, but after a nineteen day period without the drug it was resumed at 5 mg daily. This dose caused severe nausea with some vomiting, and the patient refused to cooperate by taking a reduced dose.

Eight girls from 2 to 8 years of age were given 0.1 to 0.5 mg of diethylstilbestrol daily without side effects in any case.

Each of 9 men aged 65 to 78 was given 5 mg daily. In no case was any side effect from the drug noted.

Twenty-two lactating women were given 3 to 5 mg of diethylstilbestrol daily, and although about one third had had nausea of early pregnancy there were no side effects from the diethylstilbestrol taken during this period. Two of these women who had had hyperemesis early during their pregnancy were given diethylstilbestrol at later dates with resulting attacks of severe nausea and vomiting from the drug.

In previously published research<sup>1</sup> and in some current experimentation, as yet unpublished, I have recorded considerable proof that the nausea and vomiting of early pregnancy is due to an allergic reaction of the patient to the secretion of her own gravid corpus luteum. This secretion is as yet unidentified in form but has been shown not to be progesterone. Injection of this luteal hormone intradermally in the pre-

Materials for this study consisting of "Enseris Stilbestrol" (enteric coated tablets of diethylstilbestrol), ampules of stilbestrol in oil, and special extractions of the corpus luteum were furnished by Eli Lilly & Co. through the courtesy of Dr. D. C. Hines and Dr. Raymond M. Rice of the Lilly Research Laboratories, Indianapolis.

1 Finch, J. William. Etiology of Nausea and Vomiting of Pregnancy, J. A. M. A. 111:1368 (Oct. 8) 1938. The Nausea and Vomiting of Pregnancy Due to Allergic Reaction, Am. J. Obst. & Gynec. 54:1029 (Dec.) 1940.

with nausea of pregnancy produces a typical allergic hive with surrounding erythema. In patients pregnant but with no nausea intradermal injections of this hormone produce no reaction.

In each case recorded in this paper intradermal tests were made with this luteal hormone and found to respond identically as hyperemesis patients, i. e., those with nausea and vomiting from diethylstilbestrol had positive cutaneous reactions and those without side effects from diethylstilbestrol had negative cutaneous reactions. Three nulliparas not reported in the foregoing, were very intolerant to diethylstilbestrol in 1 mg daily doses and, although they had not been pregnant, their reaction to the corpus luteum extraction was quite positive. Injections of diethylstilbestrol in oil intradermally in each case of the entire group included in this paper gave uniformly negative reactions, thus ruling out any direct sensitivity to diethylstilbestrol.

If the side effects are allergic in nature the allergen must be something produced secondary to stimulation from diethylstilbestrol or a metabolic by-product or end product of diethylstilbestrol metabolism. The first named of these is the most likely, as Greene<sup>2</sup> has shown a high percentage of cases with nausea and vomiting following large doses (comparable in estrogenic activity to the larger doses of diethylstilbestrol) of estradiol carbethoxylate, a "natural" estrogen.

#### TREATMENT OF PATIENTS INTOLERANT TO DIETHYLSTILBESTROL

Since, as stated in previous publications,<sup>1</sup> it is possible to cure the nausea and vomiting of early pregnancy with desensitizing doses of corpus luteum extracts, it was decided to endeavor to "desensitize" patients to the side effects of diethylstilbestrol by administering a course of graduated doses of the drug, hoping that they would eventually become able to tolerate a

every second or third day, beginning with 0.05 mg, gradually increasing the dose by 0.05 to 0.10 mg each dose until a total of 1 mg was reached without a reaction. Then the patient was returned to the enteric

TABLE 2—Parenteral Desensitization in Amenorrhea for Eight Months with Migraine, Nervousness and Hot Flushes

A primipara aged 33 had extreme hyperemesis of pregnancy and hyperemesis with migraine lasting for twelve hours after ingestion of 1 Mg of diethylstilbestrol.

| Date | Dose                | Reaction                                |
|------|---------------------|---|
| 7/12 | 0.15 Mg             | Severe nausea and vomiting              |
| 7/15 | 0.05 Mg             | None                                    |
| 7/18 | 0.10 Mg             | None                                    |
| 7/21 | 0.15 Mg             | None                                    |
| 7/23 | 0.20 Mg             | None                                    |
| 7/25 | 0.25 Mg             | None                                    |
| 7/29 | 0.35 Mg             | Nausea vomiting migraine                |
| 8/2  | 0.30 Mg             | Mild headache                           |
| 8/4  | 0.35 Mg             | None                                    |

| 8/26 | 1 Mg by mouth | None                       |
| 8/28 | 1 Mg by mouth | None                       |

No reaction following this date although adequate dose has been maintained for several months.

therapeutic dose. To date this desensitization process has been successfully carried out on 29 patients, 20 of them having received the desensitizing doses parenterally and 9 having taken the drug orally.

Parenteral desensitization consisted in intramuscular or subcutaneous injections of diethylstilbestrol in oil

coated tablet and given 0.5 to 1 mg daily, which dose was sufficient in most cases to produce therapeutic results.

Oral desensitization consisted in giving 0.1 mg tablets once daily for five days, then increasing the daily dose by 0.05 to 0.15 mg every five or six days until the therapeutic level required was reached. In every case the drug was well tolerated after this desensitization process. During the desensitization process, especially in the more sensitive subjects, it frequently was necessary to drop the dose back to a previous dose as further reactions to the drug were encountered. From this point the drug was again slowly increased with success. Tables 1 and 2 outline desensitization processes.

#### COMMENT

Nausea and vomiting are the most complained of side effects following administration of diethylstilbestrol, although other allergic type side effects such as urticaria and migraine are not infrequent. Of literature reviewed approximately 20 per cent of all patients treated have shown definite intolerance to this new estrogen. I myself feel that the tendency is to use far too large doses for the desired therapeutic results. Certainly many patients having side effects from 3 or 5 mg or even as little as 1 mg daily can have these side effects reduced by merely reducing the dose; however, many women are extremely sensitive to the drug, and "de-sensitization" as outlined will be necessary before they can tolerate a therapeutic dose. In one of

<sup>2</sup> Greene, I. R. Reaction to Estrogens. *Am J Obst & Gynec* 42: 58 (Nov) 1941.

merely take the time to ask the prospective patient if she had any nausea or vomiting with a previous pregnancy it should serve as sufficient warning in most cases to give not over 0.25 mg daily as an initial dose, as she will surely have side effects from a much larger dose.

Many interesting subjects for future study are suggested by these facts.

1 Is the tolerance for diethylstilbestrol by all pregnant or puerperal women due to an antihormone effect of progesterone or some other hormone or might it be due to the fact that diethylstilbestrol is more completely metabolized during pregnancy from an increased progesterone activity at that time, as the Smiths<sup>3</sup> have indicated in their work on estrogen metabolism? Or is the estrogen requirement of the pregnant or puerperal woman so much higher that diethylstilbestrol administration causes relatively little difference?

2 Is the reason that males and young girls also are quite tolerant to diethylstilbestrol due to the fact that an allergic state has not developed in these persons because of the absence of the constantly changing endocrine picture of the adult female?

3 Is the unidentified hormone of the corpus luteum which I have previously indicated the etiologic factor in nausea and vomiting of early pregnancy quite similar to a product of diethylstilbestrol metabolism or does diethylstilbestrol cause a direct stimulation of the ovary and/or adrenals simulating the endocrinology of the first trimester of pregnancy?

Several patients taking the larger doses of diethylstilbestrol have complained of the appearance of acneiform lesions on the face. These lesions disappear after withdrawal of the drug or reduction of the dose. Might this indicate stimulation of adrenal androgens?

Although all these questions obviously must be answered before the picture is at all complete, I have endeavored to show that the unpleasant side effects from diethylstilbestrol are not toxic effects per se but are an allergic response which can be corrected by a simple desensitization process.

#### SUMMARY

1 The unpleasant side effects following the administration of diethylstilbestrol are shown to occur in the same patients who also have nausea and vomiting of pregnancy. Women who have no nausea of pregnancy tolerate the drug in large doses.

2 Patients who cannot tolerate therapeutic doses of diethylstilbestrol may quickly be desensitized by frequent doses of the drug given on a graduated scale of dosage until the therapeutic dose is reached.

#### CONCLUSION

1 The intolerance of some women to diethylstilbestrol is similar to if not identical with the nausea and vomiting of early pregnancy, being an allergic reaction and occurring in the same individuals.

2 Desensitization by gradually increased doses of diethylstilbestrol will enable any patient to tolerate a full therapeutic dose of the drug.

## IDIOPATHIC RECURRENT THROMBOPHLEBITIS

WITH CEREBRAL VENOUS THROMBOSES AND AN ACUTE SUBDURAL HEMATOMA

PAUL C. BUCY, M.D.

AND

FREDERICK J. LESEMAN, M.D.

CHICAGO

Idiopathic recurrent thrombophlebitis is an uncommon but not unfamiliar disease.<sup>1</sup> Ordinarily this condition begins in men of middle age employed at sedentary tasks. The thrombophlebitis most commonly involves the superficial veins of the extremities, particularly the lower ones, but involvement of deep veins in the extremities and visceral veins is not unknown. Involvement of the cerebral veins has been suspected,<sup>2</sup> but so far as we have been able to discover the actual cerebral venous thrombooses have never been demonstrated prior to the present report.

#### REPORT OF CASE

*History*—R. A. P., a man employed in a clerical position, came under the care of one of us (F. J. L.) in 1926 when he was 37. At that time he was suffering from thrombophlebitis in one of his thighs. He had not suffered from illnesses of any moment previously except for pneumonia on the left side, complicated by empyema, which required surgical drainage in 1918. From 1926 to 1930 he suffered from recurring attacks of thrombophlebitis—first in one lower extremity, then in the other, sometimes in both. It is not now known exactly which veins were involved. During the same period he suffered from repeated attacks in which he would "choke up" and, on occasion, lose consciousness. About 1930 all these symptoms subsided completely, and from 1930 to 1941 he was well except for two or three very mild attacks of thrombophlebitis of small superficial veins in the lower extremities.

Sept. 18, 1941, at the age of 52, he had pain and tenderness in the left antecubital fossa which soon extended up the medial aspect of the left upper arm to the axilla. Three days later, on September 21, he suffered an attack in which he lost consciousness. He again consulted one of us (F. J. L.) and was immediately admitted to the Englewood Hospital. Examination revealed a thrombophlebitis of the left basilic vein extending upward into the axilla. The vein was hard, tender and painful but there was no edema of the distal part of the extremity. He had no fever and little or no generalized reaction. The remainder of the physical examination was essentially negative. The only evidence of the previous bout of thrombophlebitis was some atrophic pigmented areas in the skin about the ankles.

During his stay in the hospital the thrombophlebitis rapidly subsided, but he suffered from three attacks in which he lost consciousness, on October 1, 10 and 16. These were all similar except that they varied in duration from thirty to eighty-five minutes. Each attack began with a flushing of the face and a feeling of warmth about the head. The flushing would then descend over the entire body in a wave and the patient would lose consciousness. The eyes would bulge and the pupils dilate. The pulse would become feeble and rapid and then imperceptible, and the blood pressure would fall from the previous level of about 130 to 140 systolic and 85 diastolic to 90 systolic and 80 diastolic and frequently be unobtainable. The respirations were usually labored and often difficult or impossible to count accurately. He perspired profusely. There were

convulsive phenomenon except that on October 16, ten minutes after losing consciousness, clonic movements of the toes of the left foot and slight twitching movements of the right hand appeared. After thirty-five minutes there was some spontaneous nystagmus. The tendon reflexes were hyperactive, more so on the left side, and there was an unsustained left ankle clonus. After recovery from this attack there were no abnormal neurologic manifestations.

About October 1 he began to complain of an occasional frontal headache. The headaches became more frequent and more severe and after October 13 were present almost all the time. He vomited only twice, immediately following the attacks on October 1 and 10.

The other of us (P. C. B.) was called in consultation on October 17. A lumbar puncture had been performed earlier that morning. The cerebrospinal fluid was normal except for a slight increase in protein. Neurologic examination, October 17, revealed only that the margins of the right optic disk were blurred and the disk was elevated about  $\frac{1}{2}$  diopter. There was a small oval rose-colored hemorrhage along the upper temporal vessels just beyond the disk. The left optic disk was not elevated, but the margins were hazy and the veins were somewhat dilated. The left arm was a little weaker than the right but it had recently been the seat of a thrombophlebitis and had been immobilized. There were no cranial nerve palsies, alteration of the reflexes or sensory changes.

Following the lumbar puncture on October 17 his headaches disappeared and his condition seemed improved. On October 20 the evagrounds were unchanged. But on lumbar puncture the pressure of the spinal fluid, with the patient horizontal, was 350 mm of fluid. He was examined again (by P. C. B.) on October 24. There was a decided increase in the elevation of the right optic disk to 2 or 3 diopters, and there were many flame-shaped hemorrhages just beyond the disk, particularly along the inferior nasal vessels. There was definite though less severe choking of the left disk of  $\frac{1}{2}$  to 1 diopter but no hemorrhages. The neurologic manifestations had not otherwise altered and the pressure of the spinal fluid was still elevated.

On October 24, he was transferred to the Chicago Memorial Hospital and the following morning a ventriculogram was made. The lateral and third ventricles were shifted toward the left side and the left lateral ventricle was somewhat larger than the right.

Shortly thereafter he was returned to the operating room. A frontotemporal flap was outlined on the scalp. As soon as the first trephine opening was made the dura mater was seen to be tense and bluish green. It was incised and a large hematoma was encountered. Because the blood was firmly coagulated, the osteoplastic flap was completed in order to secure an adequate exposure. When the dura mater was reflected a large, firmly coagulated unencapsulated hematoma was exposed in the subdural space. More than an ounce (30 cc) of this blood was collected while an apparently equal amount was washed away or removed by suction. The underlying brain was soft, moderately swollen and edematous. The cortex was injected. Although most of the vessels were normal, a few of the cortical veins were distended hard and definitely thrombosed. A blunt needle inserted into various parts of the hemisphere encountered no hemorrhage or other abnormality. A subtemporal decompression was made and the wound closed.

**Pathologic Description**—The coagulated blood was examined by our pathologist Dr. Otto Saphir. Sections were made from embedded material and stained. Microscopic examination revealed nothing except recently coagulated blood.

**Postoperative Course**—Following the operation, the patient did well. The decompression bulged moderately for a time and then subsided. On October 30, five days after the operation ophthalmoscopic examination revealed a papilledema of 3 to 4 diopters in the right eye and an extensive corona of flame-shaped hemorrhages surrounding the disk. The papilledema in the left eye was subsiding. On November 2 the left eye was practically normal and the condition in the right was distinctly receding. On November 12 the left fundus

was normal. The right optic disk was flat and of good color. The margins were clear. The hemorrhages were almost completely absorbed, though some were replaced by a yellowish white exudate. The upper nasal vein extending from just beyond the center of the disk to beyond the edge of the disk was bloodless and apparently thrombosed. There was a shorter bloodless segment in the upper temporal vein a short distance beyond the disk. He was allowed up in a chair on November 6 and discharged to his home on November 12, apparently well on his way to complete recovery.

**Laboratory Examinations**—The blood counts are presented in the accompanying table.

Blood Counts

| Date                        | Red Blood Cells | Hemo globin | White Blood Cells | Poly morpho nuclears | Lympho cytes | Mono cytes |
|-----------------------------|-----------------|-------------|-------------------|----------------------|--------------|------------|
| 9/21/41                     | 4,730,000       | 95%         | 14,700            | 79%                  | 21%          |            |
| 10/24/41                    | 5,340,000       | 110%        | 13,900            | 76%                  | 24%          |            |
| 10/25/41                    | Operation       |             |                   |                      |              |            |
| 10/27/41                    | 4,600,000       | 93%         | 17,800            | 83%                  | 12%          | 2%         |
| Sulfadiazine given 10/28/41 |                 |             | 10,600            |                      |              |            |

Examination of the urine revealed no abnormality. The Wassermann and Kahn tests on the blood were negative.

The sedimentation rate with a Friedländer tube showed an 18 mm drop on October 30 in thirty minutes and on November 10 in fifty-four minutes. With this method an 18 mm drop should normally require more than two hours.

The blood coagulation time on October 18 was three minutes and on November 10 it was recorded as one minute and eleven seconds. The bleeding time on November 10 was one minute and forty-five seconds.

Examination of the spinal fluid on October 17 showed it to be clear and colorless, to contain 1 lymphocyte per cubic millimeter and 60 mg per hundred cubic centimeters of protein. Pandy's test gave a 1 plus reaction. The Kahn reaction was negative and the colloidal gold curve was 0000000000. On October 24 the results were similar except that the total protein was 37.5 mg per hundred cubic centimeters and Pandy's test showed only a trace of globulin.

Electrocardiograms taken on October 3 showed the QRS complex to be slurred in leads 2 and 3, diphasic in lead 2 and inverted in lead 3. The S-T segment was slurred in leads 1 and 2. The T wave was flattened in lead 2 and inverted in leads 3 and 4. This tracing was interpreted by Dr. A. K. Peterson as showing some evidence of myocardial damage. On October 17 the tracings were similar except that the T waves were upright in leads 2 and 4.

Ordinary roentgenograms of the skull revealed no abnormality except for small areas of calcification in the falx cerebri. The ventriculograms have been described. Roentgenograms of the chest on October 18 and October 27 disclosed that the posterior part of the left eighth rib had been resected and that there was some pleural thickening in the lower part of the thorax on the left side.

There can be little doubt that this patient belongs with the group of patients classified as sufferers from idiopathic recurrent thrombophlebitis by Barker<sup>1</sup> and others. The thrombophlebitis was certainly both recurrent and idiopathic. At the time of onset in 1926 our patient was almost 40 years of age and employed in a sedentary occupation, a situation which is highly descriptive of the average victim of this disease as reported by Barker.

There appears to be no evidence of any relationship between the pneumonia and empyema in 1918 and the subsequent developments from 1926 to 1941.

The subdural hematoma was obviously of recent origin. It was unencapsulated and had none of the cystic characteristics so commonly seen with chronic traumatic subdural hematomas. There can be little doubt that it resulted from rupture of a vein subjected

to the increased intravenous tension produced by obstruction of the venous return by a thrombus

We believe that the severe changes seen in the right fundus oculi were the result, in large measure, of thromboses of the retinal veins but that the mild papilledema without retinal hemorrhages seen in the left eye resulted from the increased intracranial pressure. This increased pressure, as evidenced by a spinal fluid pressure of 350 mm of cerebrospinal fluid, undoubtedly was secondary to the cerebral venous thromboses and the cerebral edema and subdural hematoma which they produced

Sufficient evidence is not available to permit of any statement as to the significance of the attacks of loss of consciousness in 1926-1930 except to state that they are suggestive of some cerebral involvement at that time

The four attacks of loss of consciousness in September-October 1941 are suggestive of epileptiform discharges involving the sympathetic and vasomotor systems. The various manifestations were (1) bulging eyes, (2) dilated pupils, (3) flushing, (4) profuse perspiration, (5) tachycardia, (6) arterial hypotension and (7) disturbed respiration. These are reminiscent of the symptoms present in the case which Penfield<sup>4</sup> classified as diencephalic autonomic epilepsy. Accordingly, it appears likely that our patient suffered from central venous thromboses of the brain which resulted in abnormal nervous discharges from the hypothalamus, as well as the superficial venous thromboses which were actually seen on the surface of the cerebral cortex

#### COMMENT

Idiopathic recurrent thrombophlebitis has been recognized for more than a century. Barker<sup>1</sup> credits Sir James Paget with one of the most accurate and fullest early descriptions of the condition in 1886. Those interested in a full review of the relevant literature are referred to the papers by Barker<sup>1</sup> and by Hirschhorn, Lisa and Goldstein.<sup>5</sup> Barker reported on the study of 79 cases of idiopathic thrombophlebitis, and 40 of these cases were definitely of the recurrent type. Barker<sup>1</sup> characterized the recurrent condition as beginning in men (88 per cent) of an average age of 40, although the ages of his patients at the onset of the disease varied from 21 to 67 years. Sixty per cent of his patients led sedentary lives as against 40 per cent who could be classified as physically active. Twelve per cent of his patients were Jews, a somewhat higher incidence than the percentage of Jewish patients in the clinic in which he worked. As previously stated, he found the superficial veins of the lower extremities to be most frequently involved, but on occasion thromboses were found in the arms, in the deep peripheral veins and even in the visceral veins. Barker noted moderate local pain with considerable tenderness and local redness. The involved veins were firm and cordlike. But constitutional symptoms, both subjective and the usual manifestations of infection, such as fever, leukocytosis and chill, were usually absent. Commonly the blood count, blood Wassermann reaction, coagulation and bleeding times, blood platelet counts and sedimentation rates showed no abnormality.

Barker examined segments of the involved veins microscopically and was impressed with the similarity of the microscopic picture here and in Buerger's

thrombo-angitis obliterans, the principal difference being that in Buerger's disease it is the small peripheral branches of the arterial tree that are predominantly involved, whereas here it is usually proximal veins of large caliber. This interpretation of the microscopic picture had been previously advanced by D'Abreu in 1934.<sup>6</sup> His study was based on one of the few autopsies which have been performed in this condition. D'Abreu also drew attention to the relationship between idiopathic recurrent thrombophlebitis and Buerger's disease on other grounds, and it seems not unlikely that they are really manifestations of the same disease. In D'Abreu's case, recurrent thrombophlebitis had been present for forty years before evidence of arterial disease developed, at which time the patient was 52 years of age.

Hausner and Allen<sup>7</sup> reported an interesting clinical study of 11 patients, victims of thrombo-angitis obliterans, in whom evidence of occlusion of cerebral vessels developed. They cited similar reports by Spatz, Livingston and others, and other reports of such complications are to be found in the literature.<sup>8</sup> Of particular interest in the series of 11 patients reported by Hausner and Allen is the fact that several, notably patients 1, 2, 9 and 10, suffered from recurrent attacks of thrombophlebitis of superficial veins as well as from thrombo-angitis. As theirs was a purely clinical study, it was not possible to ascertain whether the cerebrovascular disturbances were in the arterial or in the venous channels. We have found only one convincing report<sup>9</sup> of cerebral venous thromboses in a patient suffering from idiopathic recurrent thrombophlebitis. The reports by Ryle,<sup>9</sup> by Walker<sup>10</sup> and by Campbell and Morgan,<sup>11</sup> which are frequently cited as instances of this disease with such complications, are not conclusive.

Symonds'<sup>3</sup> patient, a man aged 44, had phlebitis in the left leg in January 1935. Subsequently, he suffered from headaches and vomiting. Later phlebitis appeared in the right leg. Some pelvic infection developed which on February 25 resulted in a purulent rectal discharge. The condition in the legs improved but the headache and vomiting persisted, and he occasionally complained of double vision. On admission to the hospital, April 4, there was a bilateral papilledema of 2 to 3 diopter. Visual acuity was reduced to 6/24 in the right eye and 6/12 in the left. The tendon reflexes in the left arm were somewhat more active than in the right, but there were no other localizing neurologic manifestations. Examination of the spinal fluid disclosed a pressure of 295 mm of fluid. The fluid contained 2 lymphocytes and 70 mg per hundred cubic centimeters of protein. The patient is said to have made a good spontaneous recovery. However, mention is not made of the final visual acuity or of the appearance of the optic disk. In view of the papilledema and the reduction in visual acuity, which presumably resulted from a secondary optic atrophy, one is naturally curious regarding the final state of the vision, as there apparently was

effort made to provide a persistent reduction in the increased intracranial pressure

Even in this case the evidence of cerebral thromboses is only presumptive, although strongly so. Furthermore, there are no reports of cases in which cerebral thrombosis has actually been demonstrated. We have found the reports of only 2 autopsies performed in cases of idiopathic recurrent thrombophlebitis,<sup>1,2</sup> and in neither instance was the brain examined. So far as we are aware, our case is the only one in which cerebral thromboses have actually been demonstrated as the cause of the symptoms of cerebral involvement in idiopathic recurrent thrombophlebitis. In no other instance has there been any evidence of intracranial hemorrhage, subdural or otherwise. However, in view of the well established fact that cerebral venous thrombosis is commonly associated with intracerebral hemorrhage it is likely that such has been present in some of the other cases.

#### SUMMARY

A patient with idiopathic recurrent thrombophlebitis of fifteen years' duration had symptoms of increased intracranial pressure and of hypothalamic involvement. Examination and operation disclosed a thrombosis of the retinal veins in the right eye and of the cerebral cortical veins, with a massive acute subdural hemorrhage and cerebral edema. Evacuation of the subdural hematoma and a decompression afforded immediate relief and the patient promptly recovered from his symptoms.

## GONORRHEA AT THE STATION HOSPITAL, CAMP BOWIE, TEXAS

### A STATISTICAL REPORT

MORETON A. MAGID, M.D.  
Captain Medical Corps U. S. Army  
CAMP BOWIE, TEXAS

This paper is presented to show the tremendous progress achieved in the treatment of gonorrhea and statistically the progress of the average patient in our hospital.

It is the policy of the Army to hospitalize every patient with gonorrhea for the duration of his infection. It may be that as time goes on the Army may change its policy and hospitalize only those patients who show resistance to therapy.

Before the introduction of sulfanilamide, gonorrhea was a resistant disease to cure, taking anywhere from six weeks to years. I believe that I am safe in saying that the largest percentage were cured in about three months, however, many patients with chronic gonorrhea were uncured and these took varying periods from six months on into a year or two to cure. As sulfanilamide was used the period of cure was shortened to somewhere around six weeks on the average. Then came sulfapyridine, and some of its proponents claimed that it further shortened the disease. This I cannot concur with. My experience with the drug has not been good. As a civilian urologist twice in one week I was called to see pneumonia patients who were being given the drug. Urteral colic was present in both instances and renal lavage had to be carried out. Fear of its side effects have kept me from using sulfapyridine. Fortunately, sulfathiazole has been supplied and the results obtained at this hospital are herewith presented. Sulfathiazole

is not without toxic effect at times, but the effects in this series of cases were extremely low in number and trivial in consequence. I shall make no effort to compare our results with those of other authors.

Since our patients are hospitalized until they are completely cured of their gonorrhea I might offer a suggestion or two which may shed some light on the difference in lengths of hospital stay. There are many strains of the gonococcus and some of these are definitely more virulent than others, and it is with these that we have our difficulty. Congenital anomalies of the external genitalia such as stricture and hypospadias have in the past given us trouble. Hypospadias is no longer a factor because local treatment is no longer used. Old stricture and old infected prostate glands with superimposed acute gonorrhea have been more difficult to clear up than the normal and uninfected.

Beside the patients' clinical symptoms it has been our routine practice to prove that the patient has gonorrhea by having one and sometimes two urethral smears made and stained with the Gram stain. Those patients found positive for gonorrhea have been placed on 1 Gm of sulfathiazole every four hours for the duration of their stay in the hospital until all urethral smears are negative. Before we massage the prostate, which we do as a provocative test, the patient must have three negative urethral smears. If we are unable to obtain a urethral smear we provoke a discharge by means of anterior urethral instillation of a 1:20,000 solution of mercury bichloride. After three negative urethral smears are obtained the prostate is massaged. The specimen is examined by smear for the gonococcus and by wet cell count for the number of pus cells per high power field. Before a patient is discharged he must have three consecutive negative urethral smears and two negative prostatic smears. In the event that a positive prostatic smear returns, the patient is placed on sulfathiazole again and four negative prostatic smears are obtained before he is discharged. In my wards I have insisted that daily urethral smears are made on each patient. In this manner it has been possible to note exactly when the gonococcus has disappeared.

The total number of patients cared for from Dec 16, 1940 until Dec 1, 1941 is 575. Of this number 98 were either transferred or evacuated to this station during the two maneuver periods which occurred this past year. Of this number, 63 per cent of those transferred back to their home stations were cured before orders were effective in removing them from our wards. Of the 575 patients treated there were 514 white men, 60 Negroes and 1 Indian.

One and nine-tenths per cent, or 11 patients, entered the hospital with gonorrheal complications, all of which were acute. The following complications were encountered: epididymitis, parafrenal and periurethral abscess. It is interesting to note that in only 1 instance or 0.17 per cent, did an acute epididymitis develop in the hospital. Nine patients, or 1.6 per cent, were admitted with acute gonorrheal epididymitis. They responded to treatment with scrotal elevation and an ice cap to the scrotum and sulfathiazole as previously mentioned. These patients were cured in remarkably short order, their hospital stay being no longer than the average for all patients which will be shown later. Prostatic masses were given them routinely without causing a flare up. I have been unable to find but 3 patients with cutaneous rash (0.5 per cent). 2 of these patients

receiving sulfathiazole and the other sulfapyridine. The patients on sulfathiazole were kept on the drug until they were cured of their gonorrhea. The dermatitis was not extremely severe and the patients were under constant surveillance.

Two patients (0.3 per cent) had renal colic, and the colic was proved due to showers of sulfathiazole crystals. One of these patients was taken off the drug, and although his gonorrhea persisted his colic disappeared, and on resumption of the drug mild attacks of colic appeared. This time the patient was given strict instructions to force fluids and continue taking the drug, which he did. In spite of mild showers of crystals with light colic his gonorrhea was cured. The other patient was cured of his gonorrhea just as his colic began. Microscopic demonstration of large numbers of sulfathiazole crystals in the urine was proof in these cases.

There were 2 patients (0.3 per cent) who entered the hospital with gonorrhea and complicating parafrenal abscess. One of these on incision healed and did not lengthen the patient's hospital stay. The other patient had a tremendous amount of penile edema, for which a dorsal slit was necessary. When this was done a large abscess cavity was drained along the left side of the frenulum. This cavity extended about one and a half inches (3.7 cm) down the left side of the shaft of the penis and easily admitted the forefinger along its entire length. A urinary fistula resulted and after six weeks of persistent therapy the patient absented himself without leave. The patient has just returned to the hospital. He is free of gonorrhea and a urethroplasty is contemplated.

During the August maneuvers 1 patient (0.7 per cent) was evacuated here with a perineal perineal abscess and acute gonorrhea. The abscess drained spontaneously and the patient dipped urine from the perineum for a couple of days and then the fistula closed over. The gonorrhea was cured, the stricture of the bulbous urethra well dilated and the patient discharged.

The only congenital anomaly encountered in the entire group was balanic hypospadias. There were 6 instances, 1.04 per cent, of this and in all these the external urethral meatus was large enough so that instrumentation or meatotomy was not necessary. This group of patients was all cured and discharged from the hospital in less than twelve days each.

There were 575 patients admitted with gonorrhea, of this number 553, or 96.3 per cent, had an acute attack, 10, or 1.7 per cent, had a subacute attack, and 12, or 2 per cent, had chronic gonorrhea. One patient with subacute gonorrhea was admitted with acute epididymitis. Two patients with chronic gonorrhea had acute epididymitis. One patient with chronic gonorrhea had been treated at the Station Hospital, Fort Sam Houston, Texas, for more than a year and during this period had received all types of therapy including imposed fever. In no instance has a Camp Bowie patient been readmitted and classified as having subacute or chronic gonorrhea. Every patient with subacute or chronic gonorrhea gave a history of the infection, all of whom had had treatment of some sort, mostly for a period of from three months to two years previous to induction, sulfanilamide and sulfapyridine, a few had treated themselves locally.

Of the 575 patients, 553, or 96 per cent, had acute gonorrhea. Of this number there were 8 patients who

returned to the hospital with acute gonorrhea in periods varying from two weeks to eight months after being discharged from the hospital as cured. These soldiers, 1.4 per cent, admitted exposure and in almost all cases made no effort to claim that the new infection was a prolongation of the old one. We have on record only 1 instance, or 0.17 per cent, of real acute recurrence, or possibly I should say failure to cure on first admission. This man was discharged on a Saturday morning as cured. He was confined to camp by his organization and was returned to us the following Tuesday with a profuse urethral discharge. He was again started on routine treatment and was discharged as cured eleven days later.

Of the 575 patients we were able to obtain replies as to prophylaxis in 544 instances. Eighty-two, or 16 per cent, stated that they had taken Army prophylaxis. Three hundred and sixty-two, or 84 per cent, admitted they had not.

The honesty with which any one admits fault is always questionable, however, I felt that it would be of some value to try to obtain some information as regards the incubation period of gonorrhea. Many sorts of stories were heard regarding when, how and under what other circumstances these men got their infection. I decided not to accept an exposure of more than thirty days from the time the urethral discharge appeared. Glancing over 380 acceptable incubation periods showed that the longest was twenty-eight days and the shortest one day, with the predominance between two and four days. The average incubation period for the entire group was 6.1 days.

At this point it became necessary to compile three sets of statistics in order to clarify the number of days before the patient was gonorrhea free. At first at this hospital patients were treated with sulfanilamide, later sulfapyridine and later still sulfathiazole. For the whole group the average number of days before the urethral discharge was gonorrhea free was 7.08 days, for those patients given sulfathiazole, 5.5 days. The group of patients treated by other means (52) was 20.26 days.

The average number of days that the gonorrhea patient has remained in our wards has been 12.1 days; this includes those patients treated with the older drugs. Those patients treated with sulfathiazole were hospitalized an average of 11.1 days, while the 52 patients treated before we had sulfathiazole stayed an average of 38.8 days.

Fifty blood sulfanilamide contents were run on the group of 52 patients receiving sulfanilamide. The lowest was 2 mg per hundred cubic centimeters of blood and the highest 21.1 mg, the average being 6.12 mg. The blood level of the 299 patients who were receiving sulfathiazole was 3.58 mg per hundred cubic centimeters of blood, the lowest being 1.6 mg and the highest 6.8 mg.

Of 470 patients on whom repeated prostatic smears were made there were 26 patients (5.5 per cent) who were found to have neisserian organisms present in the secretion. I can't say that this means a thing, because in no instance did complications occur as a result of the infected prostate being massaged. The disease of the patients did not become chronic and only a few more days of sulfathiazole therapy and repeated mild massage were needed, necessitating four to six more hospital days before results of tests for gonorrhea were negative and the patient was returned to duty.

## SUMMARY

1 Five hundred and seventy-five patients were treated for gonorrhea and cured between Dec 16, 1940 and Nov 30, 1941

2 Sulfathiazole has been found to be the drug of choice shortening the hospital stay of patients to 111 days

3 Side reactions to sulfathiazole were present in less than 1 per cent of all patients, and these were minimal in effect and consequence

4 The blood level of sulfathiazole has no effect on the speed of recovery from gonorrhea

5 The average incubation period was 61 days for the entire group of patients

6 The gonococcus was found to be present in the prostatic secretion of 55 per cent of our patients before they were cured

7 Duties in the hospital wards such as general policing did not produce prolongation of hospital time nor did they delay cure

## THE TREATMENT OF INCLUSION CONJUNCTIVITIS WITH SULFATHIAZOLE OINTMENT

PHILLIPS THYGESON, M D

AND

WILLIAM STONE JR, M D

NEW YORK

The rapid curative action of sulfanilamide in cases of inclusion conjunctivitis in infants and adults was described in two previous reports<sup>1</sup>. It was found that infants responded in the first few days of treatment and were usually cured within a week. In adults the papillary type of the disease responded equally rapidly, but in cases with predominant follicular hypertrophy several weeks were required for the conjunctiva to return completely to normal. The inclusion bodies characteristic of the disease could not be found after the first few days of treatment. There were no recurrences in cases in which the treatment was continued six days or longer. Local therapy with 0.8 per cent sulfanilamide solution produced temporary improvement in 1 of 2 cases but failed to effect a cure.

In spite of the demonstrable efficacy of the administration of small doses of sulfanilamide over a comparatively short period in curing inclusion conjunctivitis, the slight risk of toxic complications incident to oral medication rendered the treatment undesirable in infants, particularly in view of the benignity and self-limited nature of the disease. It seemed desirable, therefore, to test the efficacy of local sulfonamide therapy in this disease. For this purpose 5 per cent sulfathiazole and sulfathiazole sodium ointments, which had proved efficacious in the treatment of staphylococci and certain other bacterial types of conjunctivitis, were employed on the hypothesis that the drug in ointment form would reach the virus in the epithelium in a concentration sufficient to be effective and easy to maintain

by reasonably frequent applications (four to six times a day). The present report records the results obtained in the treatment of 15 infants, children and adults.

The accompanying table gives the essential data on these cases. It will be seen that in 11 of the 15 cases sulfathiazole in ointment form effected rapid cures, a result comparable in every way with that obtained by oral therapy with sulfanilamide. Just as in the sulfanilamide series, the cases in which papillary hypertrophy predominated responded more rapidly than those in which follicular hypertrophy predominated. In this respect the results were analogous to those obtained in trachoma, in which stage IIb (papillary) trachoma responded dramatically to sulfanilamide therapy and stage IIa (follicular) much more slowly.

Two patients, one a girl aged 8 years and the other a youth aged 19, both with the follicular type of the disease, failed to respond rapidly to local medication but did so when oral medication was employed. Two infants treated at home failed to respond satisfactorily within a two week period but healing was rapid when the drug was properly administered; it was found that these patients had been receiving insufficient amounts of the ointment at too infrequent intervals, probably in each instance because of the mother's language difficulties, which prevented her understanding cooperation.

There were no recurrences. In 1 case (8), six weeks after disappearance of all signs and symptoms of the disease in both eyes, a mild inflammation of the left eye developed with epiphora and secretion. Scrapings showed no inclusions and cultures revealed *Staphylococcus aureus*. The condition was found to be a lacrimal conjunctivitis secondary to a congenital stenosis of the nasolacrimal duct.

It is noteworthy that in 10 of the 11 cases that healed satisfactorily on local sulfathiazole therapy the inclusion bodies disappeared as rapidly as in those cases previously reported in which treatment was by oral medication with sulfanilamide. In these 10 cases it was impossible to find inclusion bodies after the third day of therapy. The one exception (9) was a case of the follicular type of the disease in a young girl who had contracted it in a swimming pool. In this case inclusions were still demonstrable as late as one week after onset of therapy, but the disease healed satisfactorily and has shown no tendency to recur.

In the 2 controls, both infants, the disease ran the typical course of untreated inclusion conjunctivitis in the infant, one requiring four months and the other six months to heal. Inclusion bodies were readily demonstrated in both cases during the first two months.

## COMMENT

The curative action of sulfonamide therapy in inclusion conjunctivitis has been confirmed by Allen<sup>2</sup> and by Giddens and Howard<sup>3</sup>. Lugossy<sup>4</sup> has reported favorable action but not definitely curative action. McKelvie, Kirk and Holder<sup>5</sup> refer to good results in inclusion conjunctivitis obtained by McKelvie<sup>6</sup> and recorded in the Annual Report of the Sudan Medical Service for 1938, but we have not as yet been able to

see this work Favorable but not curative results from the local use of sulfanilamide have been mentioned by Allen<sup>2</sup>

Since the virus of inclusion conjunctivitis is known to attack epithelium only, and its superficial layers most concentratedly, oral therapy would appear to have no advantage over local therapy other than that concerned with the maintenance of a constant therapeutic concentration of the drug Local applications of the drug in the form of solution, however, are of little value because of rapid dilution by tears and elimination into the nose

CONCLUSIONS

The local use of 5 per cent sulfathiazole or sulfathiazole sodium ointment was effective in causing rapid healing in 11 of 15 cases of inclusion conjunctivitis in infants, children and adults In 10 of these 11 cases the epithelial cell inclusions characteristic of the disease could no longer be found after the third day of therapy Two of the remaining 4 cases, 1 in a child and 1 in an adult, required supplementary oral therapy, the remaining 2 cases, both in infants and both treated in the outpatient department, failed to heal until the mothers

Data on Cases of Inclusion Conjunctivitis Treated Locally with 5 per Cent Sulfathiazole or Sulfathiazole Sodium Ointment

through the lacrimal passages In the 1 case previously reported by one of us in which saturated sulfanilamide solution in isotonic solution of sodium chloride was used every fifteen minutes during the day and every half hour during the night for one week, there was symptomatic cure, but the disease returned as soon as treatment was stopped The use of the drug in ointment form has the advantage of allowing its slow release over a considerable period of time In the newborn, in whom tear function is minimal during the first few weeks of life, the ointment remains visible in the conjunctival sac for considerably longer than it does in the adult This may explain in part at least the greater efficacy of local therapy in the infant than in the adult and may indicate that in the latter the ointment should be applied more often than the four to six times a day found effective for the infant

learned to employ the medication properly There have been no recurrences

Local sulfathiazole therapy would appear to be the treatment of choice in inclusion conjunctivitis, at least in the disease in the newborn infant

## Clinical Notes, Suggestions and New Instruments

### SULFONAMIDE RESISTANCE DEVELOPING DURING TREATMENT OF PNEUMOCOCCIC ENDOCARDITIS

MORTON HAMBURGER JR MD L H SCHMIDT PH D,  
J M RUEGSEGER MD CLARA L SESLER MSc  
AND EDA S GRUBEN BSc CINCINNATI

An important question raised by recent investigations of the sulfonamide drugs concerns the development of sulfonamide-resistant organisms during treatment of clinical infections. Experimental studies, both *in vivo* and *in vitro*,<sup>1</sup> have shown conclusively that sulfonamide-sensitive pneumococci can be readily converted into organisms that are highly resistant to these drugs. Available reports<sup>2</sup> suggest that this may also occur during use of the sulfonamides in treating human infections.

During a study of the clinical aspects of this problem in our laboratories a case of pneumococcic endocarditis was encountered which proved to be of special interest. The pneumococci isolated from this case at progressive intervals during treatment showed as great a change in sulfonamide sensitivity as has been produced experimentally<sup>1</sup> and a greater change than has been reported in any clinical case heretofore.<sup>2</sup> The observations on this case are summarized here.

#### REPORT OF CASE

**History.**—A Negro woman aged 43 admitted to the Cincinnati General Hospital June 16, 1941 complained of steady, aching pain in the back and right hip. This pain had been present for two days. During the previous four weeks the patient had chills, sweats, fever, anorexia and gradually increasing weakness. For about two weeks the stools had been loose and watery. There were no other symptoms, nor was there any history of recent or remote pneumonia or of rheumatic fever.

The physical examination was of little diagnostic aid. The temperature was 104 F, the pulse 120, the respiratory rate 32 and the blood pressure 110 systolic and 60 diastolic. The patient appeared chronically ill but was not in acute distress. The lungs were clear and the heart was normal except for a soft systolic murmur heard over the entire precordium. Passive movement of the right hip in any direction elicited pain, though there was neither limitation of motion nor tenderness.

The initial white blood cell count was 9,550, with 90 per cent polymorphonuclear leukocytes and 10 per cent lymphocytes. The red blood cell count was 3,250,000 and the hemoglobin 13 Gm per hundred cubic centimeters. The urine was

clear, with a specific gravity of 1.015, tests for albumin and sugar were negative, there were 1 to 2 white blood cells per high power field. Examination of the stool was negative. A roentgenogram of the chest showed an increase in the bronchial markings throughout both lung fields and a small amount of infiltrate at the base of the right lung. Roentgen examination of the pelvis revealed no abnormality.

**Course.**—The day following admission a blood culture was made which was reported positive for pneumococcus type VII. Four Gm of sodium sulfapyrazine<sup>3</sup> was administered intravenously and 1 Gm orally every four hours thereafter. After three days of this treatment a negative blood culture was obtained, but on the following day the culture was again positive. This clearing of the blood stream was accompanied by a gradual subsidence of fever, after five days of normal temperature the drug was discontinued. By that time the patient had received 134 Gm of sulfapyrazine. She looked well.

Six days passed uneventfully. On the seventh day the temperature rose to 101.8 F, and the blood culture was positive. Sulfapyrazine was again administered, and after four days of treatment the blood levels of the drug maintained between 6.4 and 16.5 mg per hundred cubic centimeters. During this interval, fifteen negative blood cultures were obtained. It is of interest that type VII pneumococci was recovered from a throat culture.<sup>4</sup> It is also of interest that the patient's serum in a dilution of 1:32 agglutinated her own organisms and produced visible swelling of their capsules. After nine days of well-being and normal temperature treatment was discontinued.

Four days later, there was a sudden temperature elevation to 105.4 F, and the blood culture was again positive. Sulfapyrazine was administered promptly and the blood culture became negative. After four days of treatment, the concentration of drug in the blood rose to 21.3 mg per hundred cubic centimeters and therapy was discontinued. Five days later, when the level of the drug had fallen to 4.8 mg per hundred cubic centimeters, the organisms reinvaded the blood, therapy was again instituted. Three days later the patient left the hospital against the advice of her physicians. Up to the time of her departure she had received a total of 307.5 Gm of sulfapyrazine.

For two weeks at home the patient's only symptoms were anorexia and weakness. Then a nonproductive cough and pain in the right axilla developed and a week later she had chills. One month after leaving the hospital, the patient reentered with a temperature of 102.6 F and a positive blood culture. Sulfapyrazine was again administered, and after four days of treatment a negative blood culture was obtained. However, with one exception, cultures made during the next thirty-six days were positive even though the level of sulfapyrazine in the blood was maintained between 12 and 30 mg per hundred cubic centimeters.

Treatment was discontinued after forty days because of the appearance of nausea and vomiting and the failure of the drug to sterilize the blood. Eleven days later 4 Gm of sodium sulfapyrazine was injected intravenously. Although this established a blood level of 21 mg per hundred cubic centimeters, the number of pneumococci in the blood did not diminish.

During the second admission the patient's condition became steadily worse. The temperature curve followed no regular pattern sometimes being normal for several days even though blood cultures remained positive. Anemia developed gradually, but there was no jaundice. Leukocytosis persisted. There were few abnormal physical signs. An apical systolic murmur increased in loudness as the anemia progressed, but no diastolic murmur ever appeared. Signs of pulmonary consolidation came and went. Roentgenograms gave the appearance of infiltrate,

<sup>3</sup> Sulfapyrazine an isomer of sulfadiazine was synthesized by Ellingson (Sulfapyrazine, Sulfapyridine and Sulfadiazine, *J Am Chem Soc* 63:2524-2525 [Sept] 1941). Its antipneumococcal activity in human and experimental infections has been reported (Ruegger, J M, Hamburger, Morton Jr, Tuttle, A S, Spies, T D, and Blum, M A, The Use of 2 Sulfanilamidopyridine in Pneumococcal Pneumonia, A Preliminary Report, *Am J Med Sci* 202:2-20 [Sept] 1941; Ruegger, G W, Clemence, L W, and Feiler, M N, Heretofore Cyclic Sulfanilamide Derivatives, *J Am Chem Soc* 63:2792-2793 [Oct] 1941; Schmidt, Ruegger, Seiler, and Hamburger). The drug used in the present study was supplied by Mehl Johnson & Co.

<sup>4</sup> Later attempts to culture type VII pneumococci from the throat were unsuccessful.

This study was aided by a grant in honor of Craig Yeiser. From the Department of Internal Medicine, University of Cincinnati College of Medicine, the Cincinnati General Hospital and the Institute for Medical Research, Christ Hospital.

though some of the films suggested pulmonary abscess. Sputum was always scanty and none of the specimens examined on five different occasions were positive for type VII pneumococci. The electrocardiogram was normal. The urea clearance was 29 per cent of normal. The nose, teeth, pelvis, hip and lungs were investigated as possible foci for the bacteremia, but these searches were fruitless. Most observers felt that endocarditis must be present.

The patient's last days were uneventful, she became gradually weaker, and fever and tachycardia persisted. She died nearly six months after her first admission to the hospital. A total of 4915 Gm of sulfapyrazine had been administered. Autopsy revealed vegetative endocarditis of the tricuspid valve, old and fresh pulmonary infarcts, subacute diffuse hepatitis and "nephrotic" changes in the kidneys.

A summary of the data relative to the blood cultures, maximum daily temperature, amount of sulfapyrazine administered and resulting levels of this drug in the blood is presented in the accompanying chart.

Curves of sensitivity of pneumococci to sulfapyrazine, blood cultures, treatment with the drug and maximum daily temperatures

#### SULFONAMIDE SENSITIVITY STUDIES

**Method**—The following procedure was used in studying the sulfonamide sensitivity of the pneumococci isolated at various periods during treatment.

Blood obtained from the patient was cultured in infusion broth containing para-aminobenzoic acid<sup>5</sup>. Organisms obtained from these cultures were subcultured at least three times in beef infusion broth enriched with rabbit blood, each transfer being incubated twelve to fourteen hours. A  $10^{-4}$  dilution of the final subculture was prepared in beef infusion broth, 1 cc quantities of this diluted culture were added to each of a series of nine tubes containing 9 cc of beef heart infusion broth<sup>6</sup> of varying sulfapyrazine content and 0.2 cc of defibrinated rabbit blood. The final concentrations of sulfapyrazine in these tubes were 0, 1.25, 2.5, 5, 10, 20, 40, 80 and 150 mg per hundred cubic centimeters. The inoculums, as determined by plate counts, varied in different experiments from 200 to 2,000 organisms per cubic centimeter of culture.

Estimations of growth were made at the end of twelve, twenty-four and forty-eight hours' incubation at 37 C. The criteria for determining growth were (1) turbidity of the culture supernatant and (2) change in the color of hemoglobin from bright red to chocolate brown. Previous experiments have

shown that these changes occur only when the population of the culture exceeds approximately 5,000,000 pneumococci per cubic centimeter. In view of the size of the inoculum, the appearance of these changes indicated that the population had increased at least twenty-five hundred fold. The results of the sensitivity tests have been expressed in terms of the highest concentration of sulfapyrazine permitting growth within forty-eight hours.<sup>7</sup>

Tests of sulfonamide sensitivity were carried out as soon as possible after isolation of the pneumococci. Since the study extended over more than five months it was necessary to use different preparations of beef heart infusion broth in the tests. That the use of different preparations of this medium does not influence the results obtained was established previously.<sup>8</sup> This has since been confirmed by tests of the sulfonamide sensitivity of stock strains of pneumococcus in at least twenty different preparations of the medium over a period of more than two years. Moreover, organisms obtained at different times during treatment of this patient were preserved and after her death were retested in a single preparation of medium. The results obtained in the retest were identical with those of the initial tests.

**Results**—The various observations on sulfonamide sensitivity are shown in the accompanying chart. Organisms isolated from the blood of the patient on the third hospital day (prior to treatment) were unable to grow in mediums containing more than 25 mg of sulfapyrazine per hundred cubic centimeters. This was also the maximum concentration of drug permitting growth of organisms isolated on the fourth and fifth days. The pneumococci obtained on days 6 and 8 grew in mediums containing 5 mg per hundred cubic centimeters. Blood cultures were negative from the eighth to the thirty-third day. Organisms obtained on the thirty-third day were unable to grow in mediums containing more than 25 mg of sulfapyrazine per hundred cubic centimeters. The organisms isolated on days 71 and 81 grew in mediums containing 10 mg of the drug per hundred cubic centimeter. Thus the decrease in the sulfonamide sensitivity of the organisms during the patient's first stay in the hospital was not great.

The next test of sensitivity was made thirty days later, i. e. two days prior to the patient's readmission to the hospital. The organisms obtained at this time showed the same response to the drug as those last tested. The culture obtained on day 113 (the day of readmission) grew only in 5 mg of sulfapyrazine per hundred cubic centimeters, but succeeding cultures obtained on days 120, 122 and 124 grew in 10 mg per hundred cubic centimeters. Thereafter there was a progressive increase in the resistance of the organisms. Those isolated between days 127 and 134 were able to grow in the presence of 20 mg of the drug and those isolated from days 138 to 150 grew in 40 mg per hundred cubic centimeters. Although rigorous treatment was discontinued on day 152 of the patient's illness, the organisms obtained on days 155 to 165 were more resistant than any isolated previously, since they were able to grow in the presence of 80 mg of sulfapyrazine per hundred cubic centimeters.

#### COMMENT

This remarkable experiment of nature afforded an unusual opportunity of studying, in the treated patient, the development of sulfonamide resistance by the pneumococcus. Development of sulfonamide-resistant organisms during treatment of pneumococcal pneumonia and meningitis has been reported heretofore, but the results in most of these studies either have been equivocal or have involved relatively small changes in sulfonamide sensitivity. In no instance has as great an increase in sulfonamide resistance been noted as in the present case.

<sup>5</sup> Para-aminobenzoic acid was not added to any medium other than that used for direct culture of the patient's blood.

<sup>6</sup> Schmidt, L. H., Hilles, C., Dettwiler, H. A., and Starks, E. The Response of Different Types and Strains of Pneumococcus to Sulfapyridine, *J. Infect. Dis.* 67: 232-242 (Nov-Dec) 1940.

<sup>7</sup> Readings taken at forty-eight hours were used in preference to those at earlier periods. This choice was based on experiments which showed that at this period variations in inoculums of the order of magnitude occurred in this study had little effect on the amount of sulfapyrazine required to inhibit growth.

The prolonged period of therapy and the nature of the disease were undoubtedly largely responsible for the high degree of resistance attained. It is noteworthy that during the early period of treatment there was little change in the sensitivity of the organisms. It, during this time, pneumococci were thrown off into the blood, they were effectively disposed of, since the blood cultures remained sterile. It seems probable, however, that as a result of prolonged contact between drug and organisms in the valvular vegetations the pneumococci slowly accustomed themselves to the presence of the drug. After this had occurred, the organisms thrown off into the blood stream were able to survive. It was then that sulfonamide resistance developed most rapidly.

There was a striking relationship between *in vitro* sensitivity of the pneumococci and the ability of the blood to sterilize itself. Negative blood cultures were maintained as long as 5 to 10 mg of sulfapyrazine per hundred cubic centimeters sufficed to inhibit growth of the organisms *in vitro*. When 20 mg or more per hundred cubic centimeters was necessary to check growth *in vitro* it became almost impossible to sterilize the blood stream, even with blood levels of sulfapyrazine as high as 30 mg per hundred cubic centimeters.

The question may be raised whether the pneumococci would have become resistant if a sulfonamide other than sulfapyrazine had been used in treating this patient. It seems improbable that the use of another drug would have altered the sequence of events. Sulfapyrazine is one of the most effective if not the most effective, of the sulfonamides against experimental pneumococcal infections,<sup>8</sup> and it has been demonstrated<sup>9</sup> that the more effective the drug the more difficult it is to develop drug resistant organisms.

It may also be questioned whether another sulfonamide could have been used effectively after resistance to sulfapyrazine was established. This was not attempted, for it has been shown that pneumococci resistant to one sulfonamide are resistant to the others as well.<sup>10</sup> Actual *in vitro* tests showed that when the organisms isolated from the present case became resistant to sulfapyrazine they were also resistant to sulfathiazole, sulfadiazine and sulpyridine.<sup>11</sup>

This case focuses attention on a serious hazard inherent in the long-continued administration of sulfonamides, whether therapeutically or prophylactically. Studies in progress in our laboratories during the last year indicate that this hazard is considerably less during short intensive treatment of acute infections such as pneumococcal pneumonia.

#### SUMMARY

A patient with an ultimately fatal type VII pneumococcus endocarditis was treated with sulfapyrazine intermittently over a period of six months. The pneumococci isolated at intervals during this treatment period showed a progressive increase in sulfonamide resistance. The organisms isolated prior to treatment were unable to multiply in mediums containing more than 25 mg of sulfapyrazine per hundred cubic centimeters, whereas those isolated after five months of treatment could grow in the presence of 80 mg of this drug. These observations point to a serious complication in the long-continued use of sulfonamides.

11 These tests were carried out both with the method described and with a blood plate method similar to that described by Auger. The results obtained with the two methods were similar. In testing the sensitivity of the organism on blood agar plates, subcultures of a moderately resistant (one hundred and eleven day) and a highly resistant (one hundred and fifty second day) strain were each streaked on half the surface of a plate and the growth compared. The difference in growth of the two strains at the higher sulfonamide concentrations was very striking.

#### ACUTE URINARY SUPPRESSION FOLLOWING SULFADIAZINE THERAPY

J. W. SCHULTE, M.D., F. P. SHIDLER, M.D., AND J. J. NIEBAUER, A.B.  
SAN FRANCISCO

Acute urinary suppression following the administration of sulfadiazine is rare but is a severe complication of use of the drug. The attendant development of uremia may lead to a fatal termination if urinary drainage is not reestablished immediately.

In a review of recent literature, urinary suppression from sulfadiazine has been reported but once.<sup>1</sup> Renal colic and both gross and microscopic hematuria have been mentioned not infrequently following its use.<sup>2</sup> So far, no cases of anuria following the administration of sulfanilamide have been reported.

The following is a report of a case in which acute urinary suppression developed following average doses of sulfadiazine.

L. E., a white man aged 26, single, American, a night club operator, entered the surgical service Feb. 23, 1942 for removal of an orbital tumor on the left side. General physical examination was not remarkable. The blood pressure was 120 systolic and 80 diastolic. There was an 8.5 mm exophthalmos of the left eye as compared with the right. There was severe papilledema with exudates and fine hemorrhages about the disk and edema extending out to and involving the macula. There was 4 diopters of choking. Only an inner upper quadrant field remained in the left visual field.

The entry blood count was 92 per cent hemoglobin (Sahli), 4.7 million red blood cells and 9,500 white blood cells with normal distribution. Urinalysis showed no red blood cells, casts or crystals. No albumin or sugar was found, and the urinary pH measured 6.0 by nitrazine paper.

With a working diagnosis of retrobulbar tumor, the left orbit was explored through a Kronlein approach on February 26. An encapsulated neurolemmoma was found and removed, but during the mobilization of the left lateral orbital wall the maxillary sinus was entered. The patient withstood the operation well. Because of the contamination of the operative field chemotherapy was begun immediately, 1 Gm. of sulfanilamide being placed in the wound.

Sulfadiazine 2 Gm. was given orally the evening of the day of operation and 1 Gm. every four hours thereafter. He tolerated the drug well. His urinary output was between 1,500 and 2,000 cc. daily during the first three postoperative days and 2,400 cc. on the fourth postoperative day. By the beginning of the fifth postoperative day he had received a total of 25 Gm. of sulfadiazine. Urinalysis on the morning of this day showed 40 to 50 red blood cells per high dry field of the centrifuged sediment and numerous typical sulfadiazine crystals. Administration of the drug was stopped. At noon the patient began to complain of abdominal pain, and by evening his pain was radiating bilaterally from the flanks toward the bladder. Fluids were forced by mouth, and an intravenous infusion of 1,000 cc. of 5 per cent dextrose was given. His fluid intake was 3,110 cc. His urinary output was only 300 cc. for this twenty-four hour period. On the sixth postoperative day he had less pain but vomited intermittently. His urine was grossly bloody. The blood pressure was 140 systolic and 90 diastolic. Two infusions of 1,000 cc. of 5 per cent dextrose were given intravenously in addition to oral fluid making a total fluid intake of 4,600 cc., 1,900 of which was lost through emesis. Only 350 cc. of bloody urine was obtained on this day. He voided 180 cc. of bloody urine early in the morning of the seventh postoperative day. Because additional urine was not passed by noon he was catheterized but no urine was obtained. That afternoon he was taken to the surgery for cystoscopy and ureteral catheterization.

From the Department of Surgery and Division of Urology, Stanford University School of Medicine.

<sup>1</sup> Thompson G. J., Herrell W. E. and Brown A. E. Anuria After Sulfadiazine Therapy. *Proc. Staff Meet. Mayo Clinic* 16: 692-612 (Ser. 24) 1941.

<sup>2</sup> Finland Strauss and Peters (cf. Finland, Lowell Strauss and J. W. Schulte, Thompson, Herrell and Brown, Plummer).

Under local anesthesia, a No 28 McCarthy panendoscope was passed. No urine was found in the bladder. The bladder was surveyed and the trigone was found to be definitely edematous, with areas of submucosal hemorrhage. The right ureteral orifice was finally identified as a mound from the center of which projected a granular mass of yellowish orange material having the appearance of crystalline deposit. The left ureteral orifice could not be identified. Several unsuccessful attempts with a small ureteral catheter were made to dislodge the plug from the right side. The cystoscope was removed and the patient was given a spinal anesthesia by injection of 50 mg of procaine hydrochloride and 20 mg of pontocaine hydrochloride. The cystoscope was reinserted and an attempt was made to dislodge the mass from the right ureter with biopsy forceps. This also failed. Five cc of indigo carmine was then given intravenously in an attempt to locate the left ureteral orifice. There was no appearance of the dye at the end of twenty-five minutes from either orifice, so a No 6 olive-tip ureteral catheter with wire stylet was used to probe the region of the left ureteral orifice. This was located under a fold of edematous mucosa, blocked by a smaller amount of the same granular substance as was seen on the right. The catheter was introduced with some difficulty and passed to the renal pelvis. A grating sensation was encountered throughout the entire distance. Twenty cc of brown, turbid urine containing a large amount of sandlike deposit was removed from the left renal pelvis and the pelvis lavaged with a total of 200 cc of warm sterile water in 10 cc amounts. The indigo carmine then appeared in fair concentration. The catheter was withdrawn and a No 8 whistle-tip catheter was passed to the renal pelvis and left in place.

Another attempt was made to dislodge the mass from the right orifice with a No 6 olive-tip catheter with wire stylet. This time the attempt was successful and the mass came away, followed by a gush of brown urine containing sandlike granular material. The catheter failed to pass beyond 5 cm, but no crystalline or calcareous deposit was encountered. Indigo carmine then appeared on that side and no further attempt was made to catheterize the right ureter. The patient was returned to the ward with the left ureteral catheter in place and a No 22 indwelling Robinson catheter in the bladder. Large numbers of typical "sheaves of wheat" crystals were seen microscopically in the first bladder urine and in the urine recovered from the left renal pelvis.

Immediately on return from the operating room the patient was given an intravenous infusion of 1,000 cc of 5 per cent dextrose and started on 4 Gm of sodium bicarbonate every three hours by mouth. During the first twelve hours drainage from the ureteral catheter measured 210 cc and from the bladder catheter 900 cc. During the next twenty-four hours 480 cc drained from the ureteral catheter and 1,835 cc from the bladder catheter. The following day 1,100 cc drained from the ureteral catheter and 1,900 cc from the bladder catheter. In view of this and also since no crystals had been demonstrated in the urine from either catheter since the day after cystoscopy, both catheters were removed on the eleventh postoperative day. His urinary output for that day and each succeeding day was well over 2,000 cc.

Treatment following cystoscopy consisted in irrigating the ureteral catheter with 5 cc of 2 per cent sterile sodium bicarbonate solution every three hours, forcing fluids by mouth and intravenous infusions of 1,000 cc of 5 per cent dextrose daily for three days. In addition, he was given 4 Gm of sodium bicarbonate by mouth every three hours. His urinary pH on daily examinations after cystoscopy was 7.0 by nitrazine test paper.

Cystoscopy was done again under spinal anesthesia four days after the first cystoscopy. At this time, intravenous indigo carmine appeared in good concentration on the right side in five minutes and on the left side in ten minutes. An attempt was again made to catheterize the right ureter, but the catheter failed to pass beyond 5 cm. Because of the prompt appearance of the indigo carmine, this apparent ureteral block was thought probably to be the result of edema or a fold of mucosa.

The blood urea was 48 mg per hundred cubic centimeters the day after his first cystoscopy. Three days later it had fallen to 18 mg per hundred cubic centimeters. The day of dismissal, seven days after his first cystoscopy, it was still 18 mg per hundred cubic centimeters.

His course after the ureteral blocks were relieved was not remarkable. His temperature rose to 39.2 C (102.6 F) on the eighth postoperative day but gradually declined to normal on the thirteenth day. The hematuria cleared rapidly and only an occasional red blood cell could be found in the centrifugated urinary specimen on the day of his dismissal. He was free of pain and abdominal discomfort on the day after the first cystoscopy. His orbital wound healed rapidly by first intention.

#### COMMENT

In this case, following administration of sulfadiazine, urinary suppression developed from ureteral obstruction by masses of crystals forming soft calculi. Apparently either crystals are formed in the collecting tubules of the kidney from which they pass to the pelvis to aggregate in large masses or through some change in the colloidal mechanism of the urine they are precipitated in the renal pelvis. This has been demonstrated by Lehr and Antopol<sup>3</sup> in studies on albino rats given massive doses of sodium sulfadiazine intraperitoneally, when they found sulfadiazine crystals in the renal tubules as early as fifteen minutes after injections of the drug.

Recently one of us performed an autopsy on a patient who died following pneumonectomy. He had received a total of 54 Gm of sulfadiazine during the eleven days before death and had a urinary output for the four days preceding death averaging less than 1,000 cc daily. At necropsy amorphous yellowish orange granular deposits were found in the right renal pelvis and along the entire course of the right ureter. This granular substance gave the typical diazo reaction of sulfadiazine. Careful histologic examination of both kidneys failed to demonstrate any crystals in the renal tubules.

In our case, the signs and symptoms of impending urinary suppression following the administration of sulfadiazine were gross hematuria, abdominal and flank pain and decreasing urinary excretion. Plummer<sup>4</sup> in a discussion on therapy at the New York Hospital reported 7 cases of gross hematuria with renal colic out of 457 cases in which 10 Gm or more of sulfadiazine was given. Flippin, Rose, Schwartz and Domm<sup>5</sup> reported 4 cases of microscopic hematuria in 200 cases in which sulfadiazine was given for pneumonia. Thompson, Herell and Brown<sup>1</sup> in their case report of anuria following sulfadiazine administration recorded microscopic hematuria and decreasing urinary output. Finland, Strauss and Peterson<sup>6</sup> reported 3 cases of hematuria in a series of 446 cases in which sulfadiazine therapy was used. Of these, 2 presented microscopic and 1 gross hematuria. The patient with gross hematuria had renal colic followed by anuria. On cystoscopy he had a ureteral obstruction which was promptly relieved by ureteral catheterization and lavage.

Large amounts of sodium bicarbonate should be given since sulfadiazine is slightly more soluble in alkaline solution. Schwartz, Flippin, Reinhold and Domm<sup>7</sup> made urinary crystal counts on 100 patients, 50 of whom were given sulfadiazine and 50 sulfadiazine, examining 290 urinary samples in all. One hundred and eighty of these were from patients receiving renal alkali and 110 were from patients to whom sodium bicarbonate was administered concomitantly in the same amounts as the

drug administered. Fewer crystals were found in the urines of patients taking sodium bicarbonate with both sulfathiazole and sulfadiazine. Curtis and Sobin<sup>5</sup> showed that acetylsulfapyridine and more particularly acetylsulfathiazole increase in solubility as the urinary pH increases in alkalinity above 7.0.

The fluid intake is most important because of the relative insolubility of the drug. In the case reported by Thompson, Herell and Brown<sup>1</sup> the average urinary output was 600 cc during the period when sulfadiazine was being administered. In our case, interestingly enough, the urinary output was more than 1,000 cc a day until the development of urinary suppression. All patients receiving average doses of sulfadiazine should be observed carefully for abdominal pain accompanied by either gross or microscopic hematuria and decreasing urinary excretion. If these symptoms and signs occur prompt cystoscopy, ureteral catheterization and pelvic lavage are indicated. A 2 per cent sodium bicarbonate solution may be used for pelvic lavage.

#### SUMMARY

1 Acute urinary suppression although rare, is a serious complication following the use of sulfadiazine.

2 Signs and symptoms of beginning renal failure are microscopic and gross hematuria, crystalluria, abdominal and flank pain, decreased urinary output and nausea and vomiting.

3 Treatment consists in forcing fluids and in alkalinizing the urine. If the urinary output decreases considerably, cystoscopy, ureteral catheterization and lavage are immediately indicated, with continuous urinary drainage by means of indwelling ureteral and bladder catheters. Subsequently, the renal pelvis should be irrigated with 2 per cent sodium bicarbonate solution every three to four hours. Catheters are removed when the urinary output has returned to normal.

4 Deposits of sulfadiazine crystals in the renal pelvis and ureters produce a mechanical anuria.

5 Sodium bicarbonate in amounts sufficient to alkalinize the urine should be administered simultaneously with sulfadiazine.

#### REPORT OF 661 NAIL PUNCTURE WOUNDS OF THE FOOT

FRED H. BOWEN, M.D. Lieutenant (j.g.) MC V(S)  
U. S. Naval Reserve  
NEW RIVER, N. C.

There is a wide diversity of opinion in the literature concerning the proper treatment of nail puncture wounds of the foot. Most authors advocate probing the wound, laying it open, injecting an antiseptic solution (phenol [carbolic acid], tincture of iodine) and instituting some form of drainage. It is my opinion that such treatment is unnecessary, painful and harmful and that it is followed by prolonged disability and

#### Disability with Reference to the Size of the Nail Involved

|                             | 6    | 8    | 10   | 16   | 20   |
|-----------------------------|------|------|------|------|------|
| Penny nail                  |      |      |      |      |      |
| No. of cases                | 205  | 209  | 86   | 61   | 19   |
| Days disability             | 10   | 71   | 124  | 111  | 84   |
| Days of disability per case | 0.04 | 0.24 | 1.44 | 1.81 | 4.22 |

This table aptly shows the increased danger of the larger nails. Perhaps the prophylactic use of one of the sulfonamide derivatives either locally or generally in the cases in which 16 and 20 and possibly 10 penny nail wounds have been incurred might be followed by a lessening of the period of disability.

at times by a painful plantar scar. Foreign bodies are not often carried deeply into the foot by a nail but they lie in the dermis or just beneath it. I have demonstrated that nails (6 to 20 penny) coated with methylosaniline (gentian violet) and driven into a cadaver's foot were wiped clean in the proximal  $\frac{1}{4}$  inch of the tract. In doing a superficial debridement

in my cases, I noted that particles of sand were just beneath the epidermis, and occasionally rust particles and little pieces of concrete or rubber were found in the same location. The introduction of a drain into a noninfected wound tends to convert it into an infected wound.

The foot is a complex anatomic unit, and several layers of fascia slide over one another when the foot is used in walking.

#### Summary of Cases with a Disability

| Cause of Disability  | No. of Days Disability | No. of Cases |
|--|------------------------|--------------|
| Soreness of foot   | 1*                     | 4            |
| Mild degree of cellulitis                                  | 2                      | 4            |
| Mild degree of cellulitis                                  | 3                      | 6            |
| Cellulitis of foot   | 4                      | 6            |
| Cellulitis of foot   | 5                      | 7            |
| Cellulitis of foot   | 6                      | 11           |
| Cellulitis of foot   | 7                      | 1            |
| Cellulitis of foot   | 8                      | 5            |
| Cellulitis of foot   | 10                     | 3            |
| Abscess of foot  | 12                     | 1            |
| Deep foot pain (traumatic osteitis?) (traumatic neuritis?) | 14                     | 1            |
| Abscess of the ball of the right foot                      | 14                     | 1            |
| Cellulitis of foot   | 15                     | 1            |
| Cellulitis of foot   | 16                     | 2            |
| Cellulitis of foot   | 18                     | 1            |
| Cellulitis of foot   | 21                     | 1            |
| Cellulitis of foot   | 42                     | 1            |

\* There were probably more patients who lost one day's work or less and did not report back to the first aid station.

Hence, by the time a patient walks from where he suffers the nail puncture wound to the doctor's office or to the hospital, these fascial planes have slid over one another so that one is dealing with a tract that resembles a staircase more than a straight line. I have attempted to follow the tract made by nail wounds in the foot of a cadaver. Walking was simulated by moving the foot between the infliction of the nail wound and the attempt to probe the tract. I was unable to follow the tract except occasionally in the wounds due to the larger nails, and it is therefore believed that probing is harmful, as it often does not follow the course of the original nail wound. In attempting to probe such a tract, one injures tissue not injured by the nail and opens new tissue planes to infection.

In dealing with cases of nail puncture wounds incurred by laborers in the construction of the United States Naval Air Station at Jacksonville, Fla., the following simple plan of treatment was used. The foot was soaked for fifteen to thirty minutes in hot water to which liniment of soft soap (tincture of green soap) or a small quantity of saponated solution of cresol was added. (I do not believe that the addition of these solutions affected the results.) The foot was dried carefully, and an area about 2 to 3 inches in diameter around the wound was painted with tincture of mercuricin (orthohydroxyphenylmercuric chloride). The wound edges were grasped with splinter forceps, and the epidermis was cut away for several millimeters about the circumference of the wound. This exposed the foreign matter (usually sand, rarely particles of sock, leather, rust, rubber or concrete), which could then easily be removed with the splinter forceps or be wiped away with a cotton applicator soaked in tincture of mercuricin. The wound was not probed beyond  $\frac{1}{4}$  inch and this was done under direct vision. A dry dressing was applied and 1,500 units of tetanus antitoxin was given. If the nail wound was caused by a nail larger than a 10 penny, the patient was instructed not to work for at least one or two days, but if a nail of lesser diameter was involved he returned at once to work. The patient was instructed to soak his foot in hot water for thirty minutes when he reached home and to repeat this at bedtime.

Patients with severe nail wounds (larger than a 10 penny or lacerated wounds) were given crêpe bandage to protect

<sup>5</sup> Curtis, A. C. and Sobin, S. S. The Solubility of Acetylsulfapyridine and Acetylsulfathiazole in the Urine. *Ann. Int. Med.* 15: 584 (Nov.) 1941.

bear weight on the affected foot for one or two days. They were told to report to the hospital on the day they returned to work for inspection of the wound. If any sign of increasing inflammation was present, elevation and rest of the affected limb with hot compresses was advised.

Patients with minor wounds were instructed to return if any increased soreness was noted.

No prophylactic sulfonamide treatment was used locally or orally.

In this paper only the patients who came for treatment on the day of the injury are considered.

Soaking the foot in hot water dilates the tissue capillaries and this brings an exudation of lymph, the best germicidal agent in the body, into the affected areas. Leukocytes are probably mobilized by the local elevation of temperature.

A total of 661 nail puncture wounds of the foot were treated by the methods outlined. There were no deaths in this series. There was no tetanus encountered in this series or in any of the thousand nail wounds treated. Cavalry units were stationed at the site of the air station during the first world war and thus the nails were probably exposed to the tetanus bacillus. There were four hundred days of disability in these cases. This is a disability per case of 0.6 day. Cases with disability due to tetanus antitoxin have not been considered in this series.

Headquarters Company, First Pioneer Battalion, Fleet Marine Force

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS HOWARD A. CARTER, Secretary

### EMERSON RESUSCITATOR HOSPITAL AND PORTABLE MODELS ACCEPTABLE

Manufacturer J. H. Emerson Company, 22 Cottage Park Avenue, Cambridge, Mass.

The Emerson Resuscitator, Hospital and Portable Models, provides for the mechanical performance of artificial respiration or for inhalation of oxygen without artificial respiration when the latter is not needed. The portable model is enclosed in a trunklike carrying case designed for use in ambulances; it weighs 43 pounds without tanks and measures 8 by 14 by 25 inches. D or E size tanks are used. The Standard Hospital model also accommodates E or D size oxygen cylinders and is mounted on an upright stand with three swivel casters having conductive rubber tires.

Working parts in the two models are identical. The complete apparatus may be said to consist of three components. The first is an automatic breathing machine employing a positive pressure of 14 mm of mercury and a negative pressure of 9 mm of mercury; the second is a device for continuous aspiration of fluid, mucus and the like from the pharynx and trachea, and the third is a device for inhalation in the administration of oxygen therapy.

Clinical evidence showing that the apparatus had been used with satisfaction and safety on infants and adults was submitted by the firm. Results of laboratory work with the unit were also presented.

Following are the results of the Council's examination.

The mechanical parts are operated by power supplied by compressed oxygen. Oxygen is supplied from small cylinders identical in construction with those generally used with anesthesia apparatus and attached in the same manner. A gage is an integral part of the equipment and indicates cylinder pressure. The reducing valve is a Linde product already Council accepted (THE JOURNAL, July 11, 1936, p. 130). This device is set to reduce the cylinder pressure to 15 pounds per square inch, at which pressure the gas is admitted to the apparatus. A valve permits adjustment by the manufacturer so that gas at this pressure will not enter too rapidly.

Oxygen entering the face mask passes over a balloon silk diaphragm to which is attached a toggle valve. As the lungs

distend against the resistance of the patient's chest wall and diaphragm a pressure is built up, to which the diaphragm of the apparatus is subjected. The toggle mechanism is so adjusted that when this pressure reaches 13 mm of mercury it shifts and closes the valve through which the oxygen has been reaching the face mask and diverts it through a Venturi tube. The side connection to this tube is simultaneously connected to the face mask and, the pressure being reduced below atmosphere by the Venturi tube, the gas moves out of the lungs. At first this is assisted by the elastic recoil of the lungs and chest walls and the pressure of the abdominal content on the diaphragm. Gradually a pressure below atmosphere is built up on the toggle diaphragm of the apparatus, and when this pressure difference reaches 8 mm of mercury the toggle reverses and the valves change so as again to admit oxygen. The toggle permits slow operation of the resuscitator and is said by the firm to operate at below zero temperatures.

Emerson Resuscitator Hospital and Portable Models

By turning a selector valve the operator may change from mechanical artificial respiration to inhalation. At the midposition of the selector valve is a connection for an aspirator tube and a bottle for trapping excess secretion. When this is in use the apparatus ceases to function either as a resuscitator or as an inhalator. To operate the aspirator a second Venturi tube entirely separate from that used to operate the artificial respiration mechanism is provided. This second Venturi tube is capable of reducing the pressure in the aspirator bottle to 140 mm below atmosphere.

In most instances artificial respiration may be successfully carried out by the Schafer prone pressure method, which does not require mechanical equipment. In addition, a simple inhalator may be used when oxygen is required. Cases of poliomyelitis in which artificial respiration is needed over periods of weeks or months require entirely different mechanism. In the opinion of the Council, devices of the type under discussion are better suited to professional than to lay use and their use by untrained persons is considered undesirable.

The Council on Physical Therapy voted to accept the Emerson Resuscitator, Hospital and Portable Models, with the understanding that such acceptance is not to be considered an endorsement of this or similar equipment for artificial respiration in the hands of the untrained laity nor in the usual uncomplicated conditions (meaning no open abdomen, broken ribs and so on) requiring artificial respiration for periods ranging from a few minutes to an hour or two.

### ALOE GLOW-BAR INFRARED LAMP ACCEPTABLE

Manufacturer A. S. Aloe Company, 1819 Olive Street, St. Louis

The Glow-Bar Infrared Lamp employs a 600 watt rod type heating element. The 600 watt element is mounted in an aluminum reflector 12 inches in diameter which is adjustable to a height of 70 inches and

Aloe Glow-Bar Infrared Lamp

which swings up, down or to either side. A screw knob on the reflector arm fixes the angle, and another screw knob locates the reflector at the desired height on the upright. Fitted over the reflector is a bronze heating element. The lamp is mounted on a black enamel tripod stand equipped with casters. The "off on" switch is located on the electric cord.

The Council found the lamp to be made and to give satisfactory service in heat therapy.

The Council voted to accept the Glow-Bar Infrared Lamp for inclusion on its list of accepted devices.

## Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT  
AUSTIN E SMITH M D Acting Secretary

### SULFAGUANIDINE RECOGNIZED AS NON-PROPRIETARY NAME FOR SULF-ANILYLGUANIDINE MONO-HYDRATE

In a previous published report, "Sulfadiazine and Sulfaguanidine Nonproprietary Names for 2-Sulfanilamidopyrimidine and Sulfanilylguanidine Respectively (J A M A 116 2019 [May 3] 1941), it was stated that the Council had recognized sulfaguanidine as the nonproprietary name for sulfanilylguanidine. Subsequent consideration brought out the fact that the compound is marketed mainly as the monohydrate. In view of this, the Council voted that the term 'Sulfaguanidine-N N R' be defined as the monohydrate of sulfanilylguanidine.

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

AUSTIN E SMITH M D Acting Secretary

**IODOBISMITHOL WITH BENZOCAINE**—A solution of sodium iodobismuthite (sodium bismuth iodide) and sodium iodide in propylene glycol (racemic 1,2 propylene glycol) containing benzocaine.

**Actions and Uses**—Iodobismithol with benzocaine seems to be well absorbed and to be excreted fairly rapidly. Intramuscular injections twice weekly produce a satisfactory therapeutic bismuth level in the blood stream as reflected in the sustained excretion level in the urine.

**Dosage**—Intramuscular injections of 2 cc repeated every three days. Two full days should elapse between injections. From sixteen to twenty injections comprise a course of treatment. In case of arsenical sensitization such therapy may be continued over a long period of time. At each injection the patient would thus receive from 0.024 to 0.0276 Gm of metallic bismuth (from 0.1154 to 0.1328 Gm of sodium bismuth iodide and from 0.218 to 0.258 Gm of sodium iodide).

#### Tests and Standards—

The specific gravity of iodobismithol with benzocaine at 25 C ranges from 1.167 to 1.175. The pH of iodobismithol with benzocaine taken with a quinhydrone electrode ranges from 4.5 to 5.0. The refractive index at 25 C ranges from 1.4609 to 1.4611.

Transfer about 3 cc of iodobismithol with benzocaine accurately weighed to an Erlenmeyer flask, add 3 cc of hydrochloric acid and 125 cc of water, determine the bismuth according to the method outlined under sodium iodobismuthite, each cubic centimeter contains the equivalent of not less than 0.012 nor more than 0.0138 Gm of bismuth. Add 10 cc of a nitric acid silver nitrate solution (prepared by dissolving 1 Gm of silver nitrate in 20 cc of water and adding 5 cc of nitric acid) to about 3 cc of iodobismithol with benzocaine accurately weighed and then add 100 cc of water, allow to stand two hours, filter into a prepared Gooch crucible and wash with very dilute nitric acid (5 cc of diluted nitric acid to make 100 cc) dry to constant weight at 100 C. Weight of silver iodide is equivalent to not less than 0.135 nor more than 0.145 Gm of iodide per cubic centimeter.

**SODIUM IODOBISMUTHITE AND PROPYLENE GLYCOL** The sodium iodobismuthite and propylene glycol in iodobismithol with benzocaine conform to the New and Nonofficial Remedies standards for these substances.

**BENZOCAINE** The benzocaine in iodobismithol with benzocaine conforms to the U S P standards for this substance.

E R SQUIBB & SONS, NEW BRUNSWICK, N J

**Ampules Iodobismithol with Benzocaine** 2 cc. Each 2 cc contains sodium iodobismuthite 0.12 Gm, sodium iodide 0.24 Gm, benzocaine 0.08 Gm, propylene glycol q s 2 cc.

**Solution Iodobismithol with Benzocaine** 50 cc rubber capped bottles. Each 2 cc contains sodium iodobismuthite 0.12 Gm, sodium iodide 0.24 Gm, benzocaine 0.08 Gm, propylene glycol q s 2 cc.

**QUININE DERIVATIVES** (See New and Nonofficial Remedies, 1941, p 403)

**QUININE DIHYDROCHLORIDE AND URETHANE**—A sterile aqueous solution containing quinine dihydrochloride U S P 127 Gm and ethyl carbamate N F 665 Gm in each hundred cubic centimeters.

For standards see U S Pharmacopeia under Quininae Dihydrochloridum and the National Formulary under Ethylis Carbamas.

**Actions and Uses**—A mixture of quinine dihydrochloride and urethane in aqueous solution is used as a sclerosing agent for injection in the obliterative treatment of varicose veins. The mixture is claimed to have antiseptic qualities. It should not be employed during menstruation, pregnancy nor in the presence of heart disease, nephritis, diabetes, upper respiratory infection or septic tonsillitis. It is contraindicated in the presence of phlebitis, suppurative ulceration and incompetence of deep veins.

**Dosage**—The initial injection should be limited to 0.5 cc to determine whether idiosyncrasy exists, average amount for injection at any one site is 1 cc and should not exceed 2 cc. The total quantity to be injected at a single sitting should not exceed 5 cc to avoid the production of cinchonism. The injection should be made slowly to avoid dangerous consequences.

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

**Ampule Solution Quinine Dihydrochloride and Urethane** 2 cc. Each ampul contains quinine dihydrochloride 0.255 Gm (4.1 grains) and urethane 0.133 Gm (2.05 grains).

**THIAMINE HYDROCHLORIDE** (See New and Nonofficial Remedies, 1941, p 551)

The following dosage forms have been accepted

SMITH-DORSEY CO., LINCOLN, NEB

**Tablets Thiamine Hydrochloride** 1 mg, 3.33 mg, 5 mg, 6.66 mg and 10 mg

**Solution Thiamine Hydrochloride** 10 cc vials, 10 mg per cc, 33.3 mg per cc, 50 mg per cc and 100 mg per cc. Each cubic centimeter contains thiamine hydrochloride in an isotonic solution of sodium chloride. Chlorobutanol 0.5 per cent added as a preservative.

E R SQUIBB & SONS, NEW YORK

**Solution Thiamine Hydrochloride** 25 cc vials 100 mg per cc. 0.5 per cent of chlorobutanol is used as a preservative.

THE LEPJOHN COMPANY, KALAMAZOO, MICH

**Tablets Thiamine Hydrochloride** 10 mg

**NICOTINIC ACID-U S P** (See New and Nonofficial Remedies 1941, p 555)

The following dosage form has been accepted

SMITH-DORSEY CO., LINCOLN, NEB

**Tablets Nicotinic Acid** 100 mg

**NICOTINIC ACID AMIDE** (See New and Nonofficial Remedies 1941 p 556)

The following dosage forms have been accepted

INTERNATIONAL VITAMIN SALES CORPORATION, NEW YORK

**Tablets Nicotinic Acid Amide** 25 mg and 50 mg

THE LAKESIDE LABORATORIES, INC., MILWAUKEE

**Tablets Nicotinamide** 50 mg

**Ampule Solution Nicotinamide, 10% W/V** 1 cc. Each cubic centimeter contains 100 mg of nicotinamide in distilled water with 0.5 per cent chlorobutanol.

**Solution Nicotinamide 10% W/V** 15 cc vial. Each cubic centimeter contains 100 mg of nicotinamide in distilled water with 0.5 per cent chlorobutanol.

S M A CORPORATION, CHICAGO

**Solution Nicotinic Acid Amide** 500 mg in 10 cc vials with 0.5 per cent chlorobutanol.

**SODIUM CITRATE** (See Revised Supplement to N N R 1941 p 26)

The following dosage form has been accepted

THE LEPJOHN COMPANY, KALAMAZOO, MICH

**Solution Sodium Citrate 2½% W/V** 50 cc ampuls. A sterile solution containing in each cubic centimeter sodium citrate-U S P 0.025 Gm (0.38 grain).

## TANNIC ACID TREATMENT OF BURNS AND LIVER NECROSIS

According to the mortality statistics of the Bureau of the Census, there were 8,083 deaths from burns in the United States in 1928, while there were 5,232 in 1933. This decrease followed the introduction of the tannic acid treatment by Davidson in 1925-1927. However, further reduction in mortality was not recorded in the succeeding four years. Improved hygienic conditions, more frequent recourse to blood or plasma transfusion and oxygen therapy undoubtedly played a conspicuous part in the lowering of the mortality in cases of severe burns. The coagulant treatment was probably a major factor in the improved results. Whether or not the favorable effect of coagulation is to be ascribed to reduction in the loss of plasma or, as Davidson himself believed, to the prevention of absorption of toxic products from the burned area is a subject of considerable controversy.

The treatment of the primary and secondary shock accompanying burns does not differ from treatment of shock in other conditions. Current research is directed to the toxic phase, which appears after eighteen to twenty-four hours. Three theories have been advanced to elucidate its cause and mode of development. 1. A physical theory, supported by Underhill, Blalock and Harkins, maintains that leakage of fluids and plasma proteins from the burned area results in blood concentration leading to circulatory failure and to anoxia. 2. A bacterial theory is favored by Aldrich, who found a beta hemolytic streptococcus in the blood and burned areas in most of his cases. 3. A chemical theory holds that a specific toxin is formed in the burned area and is absorbed into the circulating blood, with resultant toxemia and collapse.

Wilson, Macgregor and Stewart<sup>1</sup> reported in 1938 a clinical study of 65 selected cases of severe burns. Particular attention was paid to the cause of death.

<sup>1</sup> Wilson, W. C., Macgregor, Agnes R., and Stewart, C. P. The Clinical Course and Pathology of Burns and Scalds Under Modern Methods of Treatment, Brit J Surg 25: 826 (April) 1938.

Such factors as anhydremia, changes in blood chemistry and bacterial infection have been excluded as primary or etiologic agencies. These authors have studied pathologic alterations in 33 fatal cases, all treated with tannic acid. The important and characteristic pathologic lesion of acute toxemia in their studies was degeneration and necrosis of the liver cells. The lesions in the liver were much more intense than those in other organs. It appeared obvious that the liver lesion of serious prognostic importance. These investigators favor the view that acute toxemia of burns is caused by the action of a specific toxin of nonbacterial origin which has been absorbed from the burned area. The nature of the "burn toxin" has not been determined.

Belt<sup>2</sup> studied pathologic changes in 4 fatalities from burns treated with tannic acid. In each instance death ensued within four days and the liver presented "a remarkably uniform and distinctive picture." The changes in the liver were similar in all cases, with widespread necrosis producing disorganization of the parenchyma. These appearances in all 4 cases were indistinguishable from those of acute yellow fever.

McClure<sup>3</sup> reports a fatal case in which postmortem examination disclosed an almost total necrosis of liver tissue. Another patient had less toxemia, but the liver became palpable and jaundice appeared, the icterus index rising to 130 units. He agrees with Wilson, who said "After death from burns a lesion of the liver cells was found in many cases which was characteristic of this form of injury. Its relation to acute toxemia was so remarkably close as to leave little doubt that the liver lesion and the acute toxemia were produced by the same mechanism. The responsible agency was certainly not bacterial infection, and in our view the liver lesion furnished the strongest evidence of a nonbacterial toxin circulating during the first few days after a burn." McClure, however, makes the reservation that these changes might have been due to anoxemia.

Buis and Hartman<sup>4</sup> report 5 instances of death following superficial burns. The treatment included tannic acid jelly, transfusions of blood plasma and oxygen. In 4 out of 5 of these necropsies liver changes were quite similar to those described by Wilson. They state that central necrosis of the liver is regularly seen in burn cases in which death occurs three to five days after the injury. Anoxemia resulting from the shock, plasma loss, hemoconcentration and acute congestion are suggested as a contributing cause of the liver necrosis. These investigators produced in experimental animals second and third degree burns which were immediately

<sup>2</sup> Belt, Thomas H. Liver Necrosis Following Burns. Lesions of Yellow Fever. J Path & Bact 48: 493 (May) 1941.

<sup>3</sup> McClure, Roy D. The Treatment of the Burn. Burns J A M A 113: 1803 (Nov 11) 1939.

<sup>4</sup> Buis, L. James, and Hartman, F. W. Histopathology of Following Superficial Burns, Am J Clin Path 11: 220 (1941).

treated by resorcinantanol jelly, the same as that used in the clinical treatment of burns. Similar liver necrosis has been found in the experimental animals, and the lesion paralleled the extent and severity of the injury.

Wells, Humphrey and Coll<sup>5</sup> report 4 cases in which death from toxemia occurred after extensive burns. At necropsy each exhibited a central lobular liver necrosis as a prominent lesion or as the sole cause of death. Treatment consisted in a tannic acid tub debridement intravenous dextrose in isotonic solution of sodium chloride, whole blood transfusion and intranasal oxygen. They have also seen human beings with burns treated with tannic acid who have shown definite clinical and chemical evidence of liver damage but have recovered. They have injected into rats 1.5 cc of a 5 or 10 per cent tannic acid solution and produced characteristic liver damage: necrosis of liver cells in the central portion of the lobule, hemorrhage and leukocytic infiltration. The degree of damage varied directly with the total amount of tannic acid injected. Factors other than tannic acid have not entered into the production of liver damage in these experiments. The animals died largely or solely as the result of a central liver necrosis. Such a necrosis has been observed in their own cases and in those reported by others only when treatment with tannic acid has been administered. They conclude that the specific central necrosis of the liver due to tannic acid poisoning should be distinguished from the cause or causes of the so-called toxemias of burns and scalds.

Coagulant treatment is certainly not the last word on the subject. Allen and Koch<sup>6</sup> indicate that the loss of tissue fluids from the burned area in their treatment is prevented by the application of a nonadherent dressing consisting of gauze saturated with petrolatum and held in place by sea sponges and an elastic bandage. The even elastic pressure controls capillary oozing, loss of tissue fluids and formation of dead spaces. These authors voice objection to the use of a general anesthetic employed by many surgeons in the process of debriding and cleansing the burned area. They feel that a general anesthetic may act as a factor in the development of beginning shock. The mortality rate for burns at the Cook County Hospital Children's Surgical Ward for 1933 to 1936, when tannic acid treatment was practiced, amounted to 10 per cent; in 1939 with tannic acid and silver nitrate treatment it was 7.3 per cent, while under the nonadherent pressure dressing treatment the mortality rate in 1939 dropped to 5.8 per cent and under the same treatment to 3.65 per cent in 1940 and to 2.7 per cent in 1941.

#### ANNIVERSARY OF THE NATIONAL NUTRITION CONFERENCE

The National Nutrition Conference called by President Roosevelt in May 1941 assembled diversified interests in the field of nutrition and stimulated the formulation of a national program. The responsibility for coordinating the programs and activities of public and private agencies, national, state and local, into a unified program for the promotion of better nutrition rests with the Office of Defense Health and Welfare Services of which Federal Security Administrator Paul V. McNutt is director. M. L. Wilson is assistant director in charge of nutrition and Dr. W. H. Sebrell is deputy assistant director. Helen S. Mitchell is principal nutritionist.

In some states nutrition committees had been working for several years prior to the National Nutrition Conference. Others have been organized. Now active volunteer nutrition committees have been established in all the states in the District of Columbia, in Hawaii and in Puerto Rico. County committees have been organized in more than two thousand five hundred of the three thousand and seventy counties, and local committees are scattered throughout the nation. Committees are composed of trained nutritionists, physicians, dentists, public health officers and nurses, social workers and other civic leaders. These committees in most instances are affiliated with their state or local defense councils.

Throughout the nation emphasis has been placed on strengthening and expanding existing governmental programs for improving the diets of the low income groups. Through school lunch programs more than five million children received hot lunches last year. The food stamp plan enabled hundreds of thousands of families on relief to make their food dollar go further toward providing nutritious food. Low cost milk programs are now in operation in hundreds of communities.

Particular stress has been placed in the national, state and local programs on the use of enriched flour and bread. Through the cooperation of millers and bakers, following recommendations of the National Research Council, more than half the white flour and bread in the country is selling in enriched form. This percentage is constantly increasing. On April 28 the Millers National Federation recommended to the wheat flour industry the enrichment of all family flour.

Besides encouraging these programs, the state and local nutrition committees have instituted, with the cooperation of professionally trained people, nutrition classes, demonstrations and clinics, made surveys of nutrition needs in their localities and planned activities to meet the most urgent of these needs. They have secured the cooperation of libraries in providing informational materials on nutrition. Statewide nutrition conferences have been held and retre-hier courses in nutrition established in colleges and universities.

Nutrition must be as familiar to literate Americans as reading and writing. Simple, basic information has been assembled that is immediately applicable in the home. Food rules have been worked out with the guidance of the Food and Nutrition Board of the National Research Council and released in poster form, these rules list the foods to be eaten each day for an adequate, well balanced diet. These food rules are accompanied by a symbol and slogan which are intended to make the nation "nutrition conscious" and to enable all agencies, organizations and industries interested in spreading nutrition information to associate their programs with the national nutrition program.

The many channels through which the national nutrition program is being carried out may be grouped under five major headings: Nutrition Division, Office of Defense Health and Welfare Services, cooperating with related federal agencies, nutrition committees, state, county and local, state and local medical associations, food and related industries, and national organizations, civic, labor and women's groups. Many of these agencies and organizations are producing informational materials and carrying out action programs in a nationwide campaign for better nutrition. Physicians must familiarize themselves with the program and its objects so that they may contribute the scientific leadership that the public expects of them.

## Current Comment

### SCIENCE IN THE WAR AND AFTER

In times like these the search for spiritual comfort and inspiration is more necessary than in time of peace. In the midst of the world conflagration the message of Raymond B. Fosdick, president of the Rockefeller Foundation, in *A Review* for 1941, serves well to call to our attention the universality and everlasting character of scientific advancement. "The Bill of Rights," he says, "will outlast Mein Kampf just as the scientist's objective search for truth will outlive all the regimented thinking of totalitarianism." Organizations like the Rockefeller Foundation, dedicated to the extension of knowledge, can only reaffirm their undiscourageable belief in the ultimate power of reason. Much has been written of the necessity for postwar planning now. While it would seem to be folly to engage at this time in too much consideration of postwar planning, we must recognize the point emphasized by Mr. Fosdick, namely, the necessity for maintenance of fundamental education in science and of basic research. Thus he says:

This concern for the future is a matter of stern, practical sense. The specialized talents and abilities that are meeting this emergency and those that will meet emergencies to come are not produced by feverish last minute activities. No amount of pressure can suddenly create a supply of thoroughly trained and

broadly experienced physicists, mathematicians, chemists, biologists, economists and political scientists. These men represent the trained intelligence without which a war cannot be won or a lasting peace achieved. They emerge spontaneously, unpredictably but irresistibly out of long, patient and sustained effort. Pure research, the clean urge to gain new knowledge, the sympathetic appreciation of imaginative scholarship even when it seems remote and unrelated—these we must steadfastly sponsor or our vital intellectual resources will fail us in the days to come.

### GRADUATE TRAINING IN OPHTHALMOLOGY FOR LATIN AMERICAN PHYSICIANS

Further progress in Pan American relationships in the field of medical education is indicated by a recent announcement made by Dr. Harry G. Gradle, president of the Pan American Congress of Ophthalmology. Through the generosity of the W. K. Kellogg Foundation a program of graduate training has been formulated whereby twenty-five selected physicians of the Latin American countries will be brought to the leading ophthalmic institutions of the United States for a minimum of one year's training. This program of graduate training will be carried on with the cooperation of the Division of Cultural Relations of the Department of State, which has previously made arrangements whereby selected medical graduates of Central and South American countries may secure an opportunity for intern training in approved hospitals in the United States. The W. K. Kellogg Foundation has offered to pay the traveling expenses and a stipend of \$1,000 a year to the selected trainees. Eligibility requirements are such that they should assure the selection of high grade physicians who will return to their native countries at the completion of their training. Seventeen of the leading ophthalmic institutions in the United States are cooperating in this program.

### NO EXTRA GAS FOR MOTORING TO ATLANTIC CITY

The legal department of the Office of Price Administration has issued a statement that extra gasoline will not be available for physicians who are motoring to the annual session of the American Medical Association in Atlantic City, June 8 to 12. As stated previously in *THE JOURNAL*, a physician is entitled to an allowance for use in attending to his practice which permits him to use all the gasoline that may be necessary in that service. Apparently, however, it is not considered that attendance at a convention may be reckoned in relation to consumption of gasoline as a part of the practice of medicine. In replying to a question on this point, the legal department emphasized the fact that no restriction had been placed even on bishops who use gasoline so as to permit them to visit the individual ministers or priests in their dioceses, although it had been impossible to grant the use of gasoline to students who were traveling on the seaboard for graduate education. It is hoped that physicians will cooperate with the spirit of the ruling.

# MEDICINE AND THE WAR

*In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession*

## PREHABILITATION AND REHABILITATION IN INDUSTRY

WILLIAM ALFRED SAWYER, M D

Medical Director Eastman Kodak Company  
Rochester, N Y

The physical qualifications necessary to be an industrial worker are considerably less rigid than those demanded by our military forces. This point should be made very clear before an attempt is made to discuss the role that medical service for industrial workers may play in the prehabilitation and rehabilitation of men liable for service under our Selective Service System. For the Army and Navy in any of its branches a relatively high standard of physical perfection is necessary. If a fighting unit is to be successful its men must have those things inherent in first class physical condition. The requirements of military or naval operations cannot hazard the possible failure due to physical weakness or imperfection. The work to be performed by our armed forces is too critical to trust to such chances.

The human physical requisites for industry are not so exacting. In the shop and factory a man may do a high quality job standing still or while seated, although he could not perform at a task which required walking, running, climbing, lifting, pushing or pulling especially while carrying a heavy load. As long as he has his eyesight, two good arms and hands, intelligence and the endurance to stand or sit for eight to nine hours daily, he can be a satisfactory producer. Industry can use many men, physically limited for one reason or another, because the effort required is confined to only a part of their bodies, and the strain involved is geared not only to their somewhat limited capacity but for a long steady pull rather than a spurt of effort as often required in military emergencies. Physical fitness for work in industry is measured to determine ability to do a specific job, whereas in the armed forces medical examinations are given to determine fitness to perform any one of a number of jobs, in fact almost any job, hence the obvious necessity for higher standards in the services.

The program of the Selective Service System bears a certain similarity to the industrial preemployment and preplacement medical examination for the selection and classification of workers.

Perhaps an account of what is done in industry, in passing on the physical qualifications of workers might be in order.

Applicants for employment are rated as follows:

- I Physically fit for any employment. No defects or impairments.
- II Physically fit for any employment. Minor impairments easily correctable.
- III Physically fit for certain restricted employment.
- IV Physically unfit for employment (rejection).

In industry those individuals placed in class II (with correctable defects) are employed and followed periodically while working until the condition has been taken care of adequately. The common defects in this group are poor vision, infected tonsils, dental caries, anemia, underweight, overweight and so on.

Class III indicates that the individual's physical condition is such that he can do only certain types of work safely. He is employed with this understanding and is shifted to another job only with the approval of the medical department. Individuals who are industrially blind in one eye (20/100 or less) or have deformities, heart conditions, hernias and the like are included in this group. Usually the findings which put them in this class are more in the nature of permanent disabilities and are not correctable, nevertheless they can work at certain restricted jobs.

Class IV means rejections because of the more serious disabling physical impairments, conditions which make the job unsafe for the worker or his fellow workmen, and militate against his successful performance. The cause for rejection is explained to the applicant and he is asked to see his family physician or go to a hospital clinic for treatment. The majority of these handicaps are not correctable. Some could be improved or corrected if sufficient time and necessary money were available. These applicants do come back occasionally and are accepted for employment, after having extensive dental care, a hernia operation, tonsils removed, or some other major condition or infection properly treated. This demonstrates that prehabilitation is possible. It is always preferable to have physical impairments corrected before starting employment, no matter what the classification.

It is obvious that for the Selective Service System only class I men would be accepted for general military service. Many of the class II men can be made eligible for class I by medical and dental treatment in a relatively short time. The rehabilitation program more easily applies to the class II individuals.

For many years I have advocated a similar procedure in our schools. Too often young people graduate from grade or high school with remediable defects. Little if any thought has been given to the physical standards necessary to qualify them for industrial work. Every effort should be made to prepare them for the day to day routine of mass production operations—a regimen to which they have not been accustomed in their school life.

Not infrequently young boys come to industry from high school with hernias, enlarged and infected tonsils, carious teeth, poor vision and heart or lung conditions. With proper guidance these individuals could have been saved the discouraging experience of being rejected for employment until some condition has been corrected. In the past two years we have had six young men rejected on the first examination because of hernias who have had them repaired and were subsequently passed for employment. In some instances it is of course

impossible to do much in the way of correction. These handicapped individuals should have been guided and prepared for the type of industrial work best suited to them. A case in point is a young lad who was allowed to train for a machine job which required good vision. He had had considerable shop training in high school, but apparently his uncorrectable visual defect had not been discovered. His rejection for the job for which he applied might have been prevented had a thorough medical examination been given before he was advised to take up a particular field of work for which the physical requirement should have been known to the vocational guide. The disappointment to the individual and cost to the community which these rejections occasion are hard to estimate.

#### AGE GROUPS

In making comparisons it must be remembered that the age groups in industry are more extensive than under the Selective Service System. The age spread in industry not infrequently is as great as 17 to 80, whereas the Selective Service applicants have been from

industry to do everything possible to protect them from breaking down and do everything possible to rehabilitate them. Perhaps the Selective Service System will have to pursue a somewhat similar policy if the war lasts sufficiently long.

It might be worth while to review here what our physical examination consists of. It includes first of all a separate blank for a history of previous illnesses, which is filled out by the applicant and then reviewed by the nurse and the examining physician. Such a history is very helpful in uncovering conditions that are not easily detected by examination. Often past illness gives an indication of future health problems. Height, weight, eyes, ears, teeth, blood pressure, urine, heart, lungs (chest stereoroentgenogram), blood Wassermann, abdomen, hernia, feet and general body structure (musculoskeletal) are examined. Neurologic reactions are tested and any other abnormalities that would appear on inspection or palpation.

#### REJECTIONS

The two conditions causing the largest number of rejections in the Army were dental defects (19.3 per cent) and defective vision (13.3 per cent). In an analysis of the causes for rejection in our industry over a period of two years, defective vision was responsible for 23.8 per cent of the rejections and cardiac conditions for 13.6 per cent. Dental defects in themselves were not responsible for any rejections. However, there have been instances in which badly infected mouths necessitated postponing classification until the condition had been corrected. Not infrequently a combination of conditions, of which poor teeth is one, are classified as poor general condition, and this group was responsible for 6.8 per cent of the rejections. Other causes for rejection are to be found in table 1. It must be remembered that the percentages given are of the total rejections and not of the total examinations.

In 1940 and 1941 the applicants examined in one of our plants were classified as shown in table 2. Those in class I would be available for general military service without much doubt if they were in the right age group. There might be some musculoskeletal or foot conditions which we did not deem of any importance.

The class II individuals ought to be eligible for general military service if their defects were corrected. Since they consist chiefly of eyes, dental, height and weight defects, there should be relatively little difficulty. In industry we are able to persuade many of these individuals to take care of such things.

There are very few in class III and class IV who can be rehabilitated sufficiently to make them eligible for the Army. Conditions in these two classifications are more permanent.

If, however, class I and class II individuals could be made eligible, approximately 75 per cent of those examined in industry would seem, according to our standards, to be fit for general military service.

I am convinced that this group of 75 per cent could be very useful to the armed forces, at least in some capacity. Unfortunately, we do not have our records separated on the basis of age. Therefore we cannot tell what percentage of these groups are within present army age limits (21-35).

It is recorded that 6.3 per cent of the registrants under the Selective Service were unqualified because of mental and nervous conditions. No mention is made of mental conditions in the report of our rejections in industry. This is due to the sifting out of such

TABLE 1—Summary of Causes for Rejections, 1940 and First Four Periods of 1941

|                                    | Total | Percentage of Total Rejections |
|------------------------------------|-------|--------------------------------|
| Vision                             | 21    | 23.8                           |
| Hypertension and heart disease     | 12    | 13.6                           |
| Hernia                             | 9     | 10.2                           |
| Tuberculosis                       | 8     | 9.0                            |
| Poor general condition—combination | 6     | 6.8                            |
| Nervous instability                | 5     | 5.6                            |
| Positive Wassermann reaction       | 4     | 4.5                            |
| Diabetes                           | 3     | 3.4                            |
| Overweight                         | 3     | 3.4                            |
| Albuminuria                        | 2     | 2.2                            |
| Anemia                             | 2     | 2.2                            |
| Varicose veins                     | 2     | 2.2                            |
| Eczema                             | 2     | 2.2                            |
| Flat feet                          | 1     | 1.1                            |
| Gonococcal infection               | 1     | 1.1                            |
| Hyperthyroid                       | 1     | 1.1                            |
| Obstruction of nose                | 1     | 1.1                            |
| Otitis media                       | 1     | 1.1                            |
| Potential kidney disease           | 1     | 1.1                            |
| Pott's disease                     | 1     | 1.1                            |
| Undiagnosed fever                  | 1     | 1.1                            |
| Undulant fever                     | 1     | 1.1                            |

21 to 35. This obviously accounts for much of the difference in defects found. On the other hand, despite the wider age range examined in industry and the greater number of defects expected because of the older ages, industry can use a great many more of these men than can the Army or Navy.

We are told that standards for acceptance in the German army are less rigid than in our own. Perhaps that is the result of raising such a large army, or it may be that experience has taught them that men can be just as good soldiers whether they have twelve of their own teeth or necessary bridge work or dentures. Certainly dental standards in industry are not nearly so strict. If an applicant for work is free of dental infection, and it is quite obvious that he should be, and has enough teeth to carry on mastication, i. e. opposing bicuspids and molars, he is accepted.

As the demand for men in the Army increases, it is quite possible that some restrictions will be removed. Necessity dictates the possibility of many things. In industry when labor, either skilled or unskilled, is scarce, we cannot be as strict as when it is plentiful. Right now, especially as far as certain skilled workers are concerned, men are being accepted with major conditions that doubtless will make them more susceptible to lost time and disabilities. In such an emergency as the present, it is the responsibility of medical service in

to a very large extent in the employment offices. Interviewers become adept at detecting them and they are never sent for a medical examination. That eliminates the easily detected mental case. Those which we have listed as rejected because of nervous instability are cases which the employment interviewer would not be able to "spot" in conversation.

Also should be mentioned the fact that a certain number of individuals, knowing they possess some disability will not apply and submit themselves to an exacting medical examination. This fact keeps down our rate of rejections, no doubt, which for the past four years in our four Rochester plants has been as follows: 1937, 62 per cent, 1938, 25 per cent, 1939, 36 per cent, 1940, 52 per cent.

Again it should be reiterated that industry can and does use men with defects which the Army would not take. These defects in no way interfere with their general health or their ability to perform many routine occupations. Such things as the loss of a toe or a finger, or being below 60 inches in height does not militate against the performance of ordinary factory tasks. The real explanation for many of these differences lies in the fact that industry's rejection rate is negligible, 5 per cent, as against 25 per cent for the Selective Service. (Class I-A and I-B comprise approximately 75 per cent of the total.) With such a disparity in standards, it is extremely difficult to make full comparisons.

#### COMPARISON OF SELECTIVE SERVICE REGISTRANTS WITH WORKERS

The medical examination results of 157 Selective Service registrants from one of our plants, given us by one of the local draft boards, are shown in table 3. This is approximately the same as has been found generally in the summary reports of physical examinations by Selective Service local boards and Army induction stations. To be exact, these 157 Selective Service registrants with 52.23 per cent fit for military service showed a 2.23 per cent advantage over the 50 per cent of the country at large. This seemingly slight advantage might be increased considerably by a more complete analysis. However, we cannot draw any conclusions from this because we were not given the age distribution in the group of industrial registrants. It is obvious to any one supervising the health of employed workers that there is an increment of disabilities after 30 years of age. In the first examinations and inductions, men up to 35 years of age were taken which, of course, greatly increases the percentage of defects. As the rejections in Selective Service were nearly twice as great in age group from 31 to 36 as in age group from 21 to 25, no comparisons should be made except by age groups.

#### CHECK-UPS

While the original admission examination in industry is important and valuable to all concerned, it is of much greater value if it is followed by periodic check-ups. Such check-ups have proved so helpful in industry that it might be worth while to detail them here.

In some instances applicants for employment are put in class III because of such things as a hernia, infected tonsils or extensive dental caries. They are employed with the understanding that they will take care of the condition within the first year of employment and are followed periodically to make sure they are doing so. When the defect has been satisfactorily corrected they are changed to class II. The same procedure is followed

with regard to those individuals with correctable defects, put in class II at the time of the original examination. However, it is obvious that the follow-up in such cases would not be so rigid as those in class III in which there is a serious major condition.

This is a phase of the preventive work which industrial medicine strives to do. By such check-ups more serious consequences are avoided and individuals are sometimes rehabilitated and thus pushed up in their rating.

The mechanical operation of such a follow-up system is a basic consideration in its success. To insure the return of employees on the dates recommended for follow-up examinations a tickler file is maintained and is the sole responsibility of one assistant. The tickler is made out for the proper date from the original examination card with a notation of the condition to be checked. These ticklers are filed by date. Each week the ticklers dated within the week are taken out. Those individuals are called for the doctor or the nurse.

#### PREVENTION

Industrial medicine comes nearer to real personal preventive medicine than any other branch of the entire practice of medicine. I suppose it grew in large part

TABLE 2—Classification of Applicants Examined, 1940 and 1941

| Class    | 1940  | 1941  |
|----------|-------|-------|
| I        | 18.0% | 16.1% |
| II       | 56.5% | 61.7% |
| III      | 20.1% | 17.9% |
| IV       | 4.3%  | 4.6%  |
| No class | 1.1%  | 0.7%  |

out of the original safety first campaigns back in 1911-1914, when the groundwork was laid for the prevention of accidents as a result of our various state workmen's accident compensation laws. It was soon found that the doctor in industry could help reduce the severity rate of accidents by taking care of them promptly. Certainly, major infections were prevented by insisting that even the slightest injury be treated promptly by the nurse or doctor. Prevention became the watchword, and today efforts on the part of the doctor and the nurse are large factors in preventing disability and lost time, both costly wastes to employer and employee. Unfortunately, such efforts have been restricted chiefly to the larger and more successful industries.

#### SMALL INDUSTRIES

In the smaller shops and factories, adequate medical service is seldom found. If the time comes when all workers receive prompt and efficient care, then we shall have fewer disabilities and a better state of health among all our workers. By efficient care I mean adequate treatment of injuries, periodic examinations and follow-up regarding defects and disabilities with genuine efforts made toward prevention and rehabilitation.

Several years ago a plan was tried in Philadelphia, under the guidance of Dr. Glenn S. Everts of the Philadelphia Health Council, which provided part time medical and nursing service to a group of small plants. One doctor and one nurse made the rounds of these small factories periodically. Recently a great deal of attention has been given to this subject by the National Manufacturers' Association and local Visiting Nurse organizations. A number of nursing organizations have trained nurses for the purpose of providing part time nursing service for smaller industries. To what extent

small plants have availed themselves of this, there seems to be little evidence. It is a service which must be developed for the present emergency. The combined efforts of local medical societies, visiting nurse organizations and industrial groups should be able to work this out.

Small plant managers should not feel that because they cannot inaugurate complete medical service they will not undertake anything. Physical examinations of all new employees can be the first step, then perhaps examination of all present employees. It is not a question of prohibitive cost, it is a matter of interest in the preventive scheme and a will to give it a trial.

#### PROPOSED PLAN

Is it possible for industry to institute a more positive program on behalf of the Selective Service? Yes, it is. Industry could review all eligibles and offer examinations and advice concerning the correction of defects. This is already being done in a small number of cases. Men have come to our medical department and asked for examinations, so that they will know beforehand what chance they stand of being accepted. No one who

TABLE 3—Results of Physical Examination of 157 Selective Service Registrants Employed by Eastman Kodak Company (From First Thousand Registrants)

|   | Number | Per Cent |
|---|--------|----------|
| Fit for general military service          | 82     | 52.23    |
| Deferred for physical reasons as follows: |        |          |
| Teeth                                     | 16     | 10.19    |
| Cardiovascular system                     | 14     | 8.92     |
| Musculoskeletal and feet                  | 13     | 8.28     |
| Legs and feet                             | 8      |          |
| Arms and hands                            | 2      |          |
| Back injury                               | 2      |          |
| Dislocated hip                            | 1      |          |
| Vision                                    | 10     | 6.37     |
| Lungs                                     | 6      | 3.82     |
| Hernia                                    | 4      | 2.54     |
| Underweight                               | 3      | 1.91     |
| Ears                                      | 2      | 1.27     |
| Inguinal rings                            | 2      | 1.27     |
| Diabetes                                  | 1      | 0.64     |

is genuinely interested in entering the service likes to be "turned down." Those whose patriotism and sense of duty convince them that they ought to get into one of the services as soon as possible will welcome an opportunity to correct disqualifying conditions. Some, no doubt, will be glad to bear the cost of having conditions corrected.

Perhaps this is a phase of industrial medicine which has been neglected. Unfortunately, it has been the practice of industry to concern itself very little with the individual who cannot pass its applicant examination. Nor does it do enough in encouraging those admitted for employment to have correctable impairments treated while employed, thus improving their health. This situation exists largely because there are not the proper arrangements and funds to take care of it. It is one of those steps in the evolution of a complete medical service for workers that is yet to be developed. Possibly the attention directed to it by the rejections under the Selective Service System may bring about a solution.

While it is true in our Kodak organization that we have aided some applicants who could not pass the entrance medical examination to have defects corrected, there has been no well developed program. Usually it has been an individual matter between the examining physician and the applicant who has evinced a desire to

have something done. Some persons want a job so much that they insist on knowing how they can eventually qualify. So often a man will say "Well, does this turn me down forever? Isn't there anything I can do about it?" Perhaps they did not know they had a disqualifying condition. Sometimes they are grateful for knowing, and even though they do not have the ready money to have any extensive medical treatment they will ask for advice as to how it may be accomplished. It is this sort of person that most physicians will instinctively try to help.

It might be of interest to tell briefly of the attempt in Rochester last year to rehabilitate a group of trainees attending vocational classes for war industries, under the Federal Emergency Defense Training Act. The project included not only medical examinations but also follow-up of the physically disqualified, in an effort to help them have defects corrected.<sup>1</sup> These reports, with their analysis of 2,791 examinations, their ratings, rejections and attempts at rehabilitation, show that approximately 33 per cent were disqualified for defense industry employment, 60 per cent of these voluntarily sought the Medical Consultant Service set up by this combined community enterprise, and 85 per cent of the 547 men in class III and class IV who saw the consultant had conditions sufficiently corrected to be passed for employment. This experience demonstrated that applicants for jobs are interested in making themselves physically eligible and that physicians will cooperate in helping such persons to get the necessary treatment. Ophthalmologists contributed their services without remuneration. Other physicians rendered certain services gratis, either in the hospitals or in their offices. This was all very commendable but is not a satisfactory solution to the problem.

What plan can industry devise which will insure a higher percentage of physically sound workers and also help to prehabilitate those who may be drawn from the ranks of industry by the Selective Service System? This seems a propitious time to propose a plan, in part suggested by Col. L. G. Rowntree, Chief of the Medical Division of the Selective Service System. When an applicant for a job is rejected and told he cannot be accepted until certain impairments are taken care of, would it be possible to issue a card or letter saying that the bearer has been examined for employment but that, because of certain specific conditions, it is impossible to accept him until they are corrected? Such a letter as this might be given to the applicant:

Dr

was examined by us today for

a job as

Because of the following conditions, he did not pass our examination

If you will assist him in having these conditions corrected, we shall be glad to consider him again for employment. It must be understood that it is not possible to hold jobs open for any length of time, and no promise can be made that this particular job with us will be available when he presents himself again for examination. Every effort will be made to offer him a job when he is ready. It is to his interest and well that his health be improved as early as possible.

Yours truly,

<sup>1</sup> Greenman, Raymond H. Health for Industrial Training. Midmonthly Sawyer, W. A. Medical Aspects of Vocational Training. J. A. M. A. 118:641 (Feb. 21) 1942.

By arrangements with the members of the county medical and dental societies and the hospitals, it should be possible to put such a plan into operation. Industry could not guarantee payment for this medical service, but the fact that the individual had been considered for employment by a reputable concern ought to be a recommendation to the doctor or hospital to extend credit as far as possible to such a person. The least that the medical profession, the dentists, the hospitals and other interested groups can do is to assist in putting persons with substandard physiques into condition to work safely and successfully.

It is always possible to find some way to help the occasional individual to secure needed medical service. Very few industrial communities are lacking in sufficient facilities. The trouble comes when there are so many cases that it becomes a burden. Such reconditioning will not function equitably and smoothly without a well integrated plan in which all groups cooperate. The hospital and the doctors cannot do much rehabilitation without remuneration. Most of the workers want to pay, but they cannot afford to pay much or promptly. If doctors or the hospitals extend credit to workers to help put them in better physical condition, industry can exert some influence in persuading the worker to pay his bill. As far as older employees are concerned, industry not infrequently lends them money to pay medical (rehabilitation) bills. This should all be worked out on a broad, comprehensive scale, retaining as far as possible the usual doctor-patient relationship along with freedom of choice of doctor, dentist and hospital. Naturally,

the financial side must be planned for. As usual, the members of the medical and dental professions will be willing to make some gambles in so worthy an effort. Such a project might encourage workers to apply for treatment to the best men rather than the cheapest.

At present there may be more interest in the prehabilitation and rehabilitation of men who can be made available to the military forces, and this must be the first necessity, but whatever works with industry ought to benefit the prospective armed service candidates. A basically sound plan should have a broad application to both.

Providing essential materials and arms for military purposes is quite as necessary as securing the right men properly trained, to use them. To do this efficiently and with speed, it is fundamental that we have healthy, normal workers. If many workers are drawn into the military service and they have been rehabilitated, the armed forces will be so much the gainer. Workers must be kept fit and on the job. Especially is this important when we remember that it takes eighteen men behind the lines for every able bodied man in the armed ranks. Efficient efforts by industrial medicine show a reduction in the amount of absence due to sickness. Disabilities are shortened and prevented. Therefore, the great opportunity of industrial medicine at this time, as a part of the war effort is to improve and maintain the health of workers. By practicing prehabilitation and rehabilitation, it will be making a real contribution to our present man power requirements both in industry and in the military services.

#### EXAMINATION FOR APPOINTMENT IN MEDICAL CORPS, REGULAR ARMY

The War Department announces an examination, August 10-13, for the purpose of qualifying candidates for appointment as first lieutenants in the Medical Corps, Regular Army, to fill vacancies occurring during the fiscal year 1943. The examination is open to all male graduates of acceptable medical schools in the United States and Canada who have completed one year's internship in an approved hospital and who will not be over 32 years of age at the time it will be possible to tender a commission. Candidates who fail a first examination will not be permitted to take more than one subsequent examination. The examination will be conducted by boards of medical officers and will consist of a physical examination, a written examination in professional subjects and a determination of the candidate's adaptability for military service. Full information and application blanks will be furnished on request addressed to the Adjutant General, War Department, Washington, D. C. Applications will not be considered if received in the War Department after July 22.

#### COMMISSIONS FOR MEDICAL STUDENTS

The War Department issued the following instructions, May 12:

1 Reference is made to War Department Immediate Action letter AG 210 1 MA-AUS (4-25-42) RB-SPGA, May 8, 1942, above subject. (See THE JOURNAL May 23 p. 352)

2 The following instructions are published relative to the action to be taken in reference to students who are members of the R O T C advanced course in R O T C units of the arms and services other than Medical Corps and who become accepted matriculants in an approved medical school:

a Students who prior to entrance in an approved medical school will have completed all requirements for a commission including summer camp training will be commissioned in the arm or service in which training was received.

b Students who, prior to entrance in an approved medical school, will have completed all requirements for a commission

except training at the appropriate service school, will be governed by the following:

(1) Where the date of entrance in an approved medical school will permit students will be required to attend the prescribed course at the appropriate special service school. On successful completion of this course, they will be commissioned in the arm or service in which training was received.

(2) Where the date of entrance in an approved medical school will not permit attendance at the appropriate special service school will not be required and students will be permitted to withdraw from their advanced course contracts for the convenience of the government.

c Students who enter an approved medical school prior to the completion of the senior year of the R O T C advanced course will be permitted to withdraw from their advanced course contracts for the convenience of the government.

3 Students who, under the above provisions are commissioned in an arm or service other than the Medical Corps, will not be ordered to active duty except as provided for in the letter referred to in paragraph 1, above.

4 Students who are permitted to withdraw from their advanced course contracts for the convenience of the government will not be required to refund any sums previously paid to them as commutation of subsistence.

By order of the Secretary of War

J A ULIO  
Major General,  
The Adjutant General

#### THE SALVAGE OF TIN

The War Production Board on May 20 announced that the Metals Reserve Company has designated the Tin Salvage Institute of Newark, N. J. as the only organization authorized to salvage the tin tubes accumulated by retailers in connection with the sale of new tubes or tooth paste and shaving cream. Retailers will turn over free of charge to their nearest wholesale supplier the tubes which they have collected but in such facilities are not available retailers may ship the tubes collected in lots of 5 pounds or more to the wholesale supplier.

will be reimbursed for the freight charges by the institute Chain stores, junk dealers, warehouses, wholesalers, organizations and others having large stocks of old tubes may ship lots of 100 pounds or more to the Tin Salvage Institute, 411 Wilson Avenue, Newark, N J, freight collect On termination of the agency with the Metals Reserve Company, the Tin Salvage Institute will wind up its affairs and formally dissolve

### PLAN FOR COLLEGE STUDENTS TO ENLIST IN RESERVE AND CONTINUE STUDIES

The War Department announced on May 14 its Army Enlisted Reserve Corps plan whereby selected qualified college students may continue their college education for the time being on an inactive status The plan provides for the enlistment in the Army Enlisted Reserve Corps of a certain number of qualified men in colleges all over the United States These men are encouraged to continue their education in order that they may be better prepared to serve their country, especially in branches of the service requiring technical knowledge An examination will be given during the second year, and those who do not meet the required standards or who have not given promise of a capacity for leadership will be immediately called to active duty It should be understood that men in the enlisted reserve may be called to active duty at any time required by the military situation

The first requisite for enrolment in the Army Enlisted Reserve Corps will be United States citizenship Enrolment will be voluntary The student must evidence the basic qualities necessary for commissioned rank, be physically qualified and must have attained 18 years of age If a student fails to graduate with his class, fails to meet the prescribed level in the qualifying examination or withdraws from school or fails to show the qualities for officer material, he will be reported to the corps area commander and will be ordered to duty in an enlisted status

On graduation, physically qualified students who are members of the corps will be ordered to active duty and sent to the nearest reception center as privates, after completing the normal course of basic military training they will, if otherwise qualified and selected, be eligible for admission to an officer candidate school Students specially qualified for advanced study or research or as faculty replacements may be recommended by the institutional authorities to continue their studies, and on approval such students will be continued in the corps in an inactive status

This plan does not alter the continued operation of the present R O T C system

### NATURALIZATION OF NONCITIZENS IN THE ARMY

The War Department has directed (Circular Letter No 120, April 24, 1942) all commanding officers to take action to facilitate the naturalization of noncitizen members of their commands who desire to become citizens and, for this purpose, to establish liaison with the nearest district office of the United States Immigration and Naturalization Service To be eligible for naturalization under the provisions of the act cited in Circular Letter No 120, a noncitizen in the army must have been lawfully admitted into the United States or its possessions and must have been a resident there at the time of his entry into the service He must have given honorable service for at least three months, be of good moral character and, in the opinion of his immediate commanding officer, would make a loyal and useful citizen of the United States The requirement of at least three months' service may be waived when the applicant is scheduled to depart for overseas service Naturalization procedures will be completed before departure for overseas for all noncitizens desiring to become citizens Noncitizens in training at replacement training centers who desire to become citizens will be naturalized before their departure from the replacement training center All noncitizens passing through reception centers will be sent to replacement centers and will not, except under unusual circumstances, be sent direct to units from reception centers

The requirement of three months honorable service during the present war will be waived for noncitizens who were former citizens of the United States and who lost their citizenship by reason of service in the armed forces of an allied nation during the first world war or second world war

### ARMY APPLICATIONS OF DENTISTS

The army is now prepared to accept the applications of three thousand dentists who are in class 1-A of the Selective Service, according to a memorandum from Sam F Seeley, executive officer of the Procurement and Assignment Service Applicants should write immediately to the Surgeon General for application forms Only those in class 1-A need apply They need not wait for notification by their board to appear for induction examination The sooner a man enters the service, the greater his opportunity to advance as the army expands Every candidate will be cleared through the Procurement and Assignment Service

### VETERINARIANS, IF DRAFTED, TO BE COMMISSIONED

The Procurement and Assignment Service announced that the veterinary service is now completely staffed and has a large reserve of officers which is adequate to meet the needs for the rest of the calendar year For this reason there are no vacancies in the Veterinary Corps of the U S Army However, the civil need for veterinarians is great and it is desired that no veterinarians be inducted into the military services in the capacity of enlisted men In order to conserve all veterinarians in a professional capacity, the Surgeon General of the Army has announced that any veterinarian who is inducted will receive a commission if he meets the professional requirements There fore any veterinarian who has been drafted should apply immediately to the Office of the Surgeon General for the necessary forms for application for a commission

### FIVE MORE GENERAL HOSPITAL UNITS ACTIVATED

The War Department has authorized the activation in May of five additional general hospital units 6th Massachusetts General Hospital Unit, Boston, 20th University of Pennsylvania Unit, Philadelphia, 30th University of California Unit, San Francisco, 38th Jefferson Medical College Unit, Philadelphia and 45th Medical College of Virginia Unit, Charlottesville, Va The total bed capacity of these hospital units will be four thousand six hundred beds The commanding officer of the 20th is Lieut Col Isidor Ravdin, Philadelphia, of the 38th, Lieut Col Baldwin L Keyes, Philadelphia, and of the 45th, Lieut Col Carrington Williams, Richmond, Va

### MEDICAL AND SURGICAL RELIEF COMMITTEE

During the last month the Medical and Surgical Relief Committee of America, with headquarters at 420 Lexington Avenue New York City, has furnished more than forty-three emergency medical field sets to defense officials and hospitals throughout the country All bandages used in these field sets are made up by the American-French War Relief Committee and sterilized and packed into units by the Hospital for the Ruptured and Crippled in New York The committee urgently requests that its members thoroughly canvass all hospitals and other sources in their respective localities for surplus scissors, which are needed to complete the contents of emergency medical field sets

### PLAGUE INFECTED RATS IN HAWAII

The Public Health Service in Hawaii has maintained a plague suppressive service which in the last three months 1941 destroyed more than 41,000 rodents, of which nearly 2,000 were examined in the laboratory, and of these 23 were found with rodent plague There were no cases of human plague during this period

# ORGANIZATION SECTION

## OFFICIAL NOTES

### THE ATLANTIC CITY SESSION

#### Conference on Motion Pictures

The Committee on Scientific Exhibit has authorized a conference on medical motion pictures to be held during the annual session of the American Medical Association in Atlantic City.

Among the subjects to be discussed will be information on the availability and listing of motion pictures, the utilization of films in medical schools and medical societies, the distribution of films through film libraries and other sources, the production of new films and how they can be made to fill the need of medical teaching.

The conference will take place on Wednesday June 10 at 3 30 p m in room F in the Atlantic City Convention Hall. The chairman will be Dr W L Benedict of Rochester, Minn.

#### Conference on Conservation of Vision

In compliance with the terms of a resolution submitted to the House of Delegates at the annual session of the Association held in 1940, a Committee on Conservation of Vision was appointed. In view of the great scope of the duties assigned to that committee it is believed to be highly desirable that the committee should have the benefit of suggestions and advice of a much larger group than is comprised in the members of the committee. It is therefore proposed that a conference be held at the Hotel Traymore at 2 p m Wednesday, June 10, for the purpose of discussing a proposal to enlarge the Committee on Conservation of Vision and Prevention of Blindness so that each state in the Union may be represented and for the further purpose of discussing a tentative program of work.

The members of the Committee on Conservation of Vision and Prevention of Blindness are Drs S Judd Beach, Portland, Maine, Harry S Gradle, Chicago, Albert C Snell, Rochester, N Y, Lawrence T Post, St Louis, Arthur J Bedell, Albany, N Y, and Olin West, Secretary and General Manager of the American Medical Association.

The proceedings of the conference will be submitted to the Section on Ophthalmology so that recommendations may be properly submitted to the House of Delegates.

#### The Golf Tournament at Atlantic City

The Atlantic City Golf Committee has made arrangements for the twenty-eighth annual tournament of the American Medical Golfing Association to be held at the Seaview Country Club on Monday June 8. American Medical Golfing Association fellows may play this club on one or more days preceding the tournament by paying a regular green fee of \$3 a day and a special prize will be awarded on June 8 if such players will hand in their score cards to the club office. The total cost per person for an excellent dinner, the tournament fee, green fees and prizes is \$7.50. New fellows of the golfing association pay an additional enrolment fee of \$3. The taxi fare to the club from the boardwalk hotels a distance of 9 miles, has been reduced to \$2.50 for four or fewer persons. The club has sleeping accommodations for one hundred and fifty guests, a first class restaurant and a salt water swimming pool. Members desiring hotel accommodations at the Seaview Country Club should write to Mr John F Reid, Manager, Seaview Country Club, Absecon, N J. Nearly fifty trophies and prizes for experts, clubs and beginners in both gross and net events will be awarded. Only active fellows of the American Medical Golfing Association may compete for the prizes. The executive secretary is Bill Burns, 2020 Olds Tower, Lansing, Mich.

### Are You Flying to the Meeting?

If so, you should know that there is no airport in Atlantic City. All flights of all lines make use of the Philadelphia municipal airport. Limousine service from the airport to the Broad Street Station, Philadelphia, is available. The distance is 8 miles and the cost, including tax, is 80 cents. Forty-five minutes is allowed for the trip.

#### Service from Broad Street Station to Atlantic City

The Pennsylvania-Reading Seashore Lines operate out of Broad Street Station, Philadelphia, on the following schedule.

All times are subject to change without notice.

| Leave Broad Street | Week Days | Arrive in Atlantic City |
|--------------------|-----------|-------------------------|
| 8 15 a m           |           | 9 45 a m                |
| 10 30 a m          |           | 11 50 a m               |
| 12 30 p m          |           | 1 50 p m                |
|                    |           | (Saturdays only)        |
| 1 30 p m           |           | 2 50 p m                |
|                    |           | (Saturdays only)        |
| 1 30 p m           |           | 3 00 p m                |
|                    |           | (Except Saturdays)      |
| 4 30 p m           |           | 5 55 p m                |
| 5 25 p m           |           | 6 45 p m                |
| 8 35 p m           |           | 10 00 p m               |
| 11 45 p m          |           | 1 10 p m                |
|                    | Sunday    |                         |
| 8 40 a m           |           | 10 00 a m               |
| 10 30 a m          |           | 11 50 a m               |
| 11 50 a m          |           | 1 15 p m                |
| 1 30 p m           |           | 2 50 p m                |
| 4 30 p m           |           | 5 55 p m                |
| 8 35 p m           |           | 10 00 p m               |
| 11 45 p m          |           | 1 10 p m                |

#### Special Trolley to Carry Physicians to Combined Luncheon

There will be a special trolley at Georgia and Atlantic avenues, Atlantic City, on Tuesday June 9 at 12 05 p m to carry members of Rotary, Kiwanis, Lions, Reciprocity and Exchange Clubs to Hackney's Restaurant for a combined luncheon meeting with local members of these groups. The speaker at the luncheon will be Dr Perrin H Long of Baltimore, whose subject will be "Medicine and the War Effort."

#### George Washington University Alumni at Atlantic City

A luncheon meeting of graduates of Columbian and George Washington University will be held at the Claridge Hotel, Atlantic City, Wednesday June 10 at 12 30 p m during the annual meeting of the American Medical Association. Tickets will be \$1.50. The secretary-treasurer of the George Washington University Medical Society is Dr Oscar B Hunter, 1835 Eye Street N W, Washington, D C, to whom requests for reservations may be addressed. Please do not send any money.

#### Physicians' Art Association Dinner

A dinner has been arranged by the president of the American Physicians Art Association, Dr Robert Ridpath, Philadelphia, to be held at the Hotel Claridge, Atlantic City, Tuesday June 9 at 6 30 p m in honor of Mr and Mrs A L Root of Meriden, Conn., and Company, sponsors of the art exhibit. The seventy-five trophies will be awarded to the winners at this dinner. Members desiring to participate in the art exhibit should ship their art pieces early in care of the secretary of the American Physicians Art Association, Dr F H Redewill, Hotel Claridge, Atlantic City, N J. All art pieces should be sent preferably by railway express collect.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

### CALIFORNIA

**Society News**—Dr. Leo Eloesser, San Francisco, addressed the Hollywood Academy of Medicine, April 9, on "War Wounds"—Dr. Ralph R. Mellon, Pittsburgh, addressed the Los Angeles Surgical Society, April 10, on "The Sulfonamide Drugs in Wound Healing."

**Gold Headed Cane Awarded**—Henry Donald Grant, Healdsburg, is the recipient this year of the Gold Headed Cane, the annual honor award to a member of the graduating class of the University of California Medical School, San Francisco. The cane is awarded to the senior student who, in the opinion of his classmates and the faculty of the division of medicine, has demonstrated the most outstanding qualities of a physician and who has shown the greatest interest in the care of his patients during his clinical years.

**Heart Disease Publicity**—The California Heart Association and its chapters in San Francisco, Los Angeles and San Diego have launched an educational program against heart disease, including the use of street car posters and free distribution to parent-teacher and other groups of exhibits, study group outlines, films, radio scripts and speakers. The Los Angeles Tuberculosis and Health Association has established a division of heart diseases with a budget which will permit employment of a health education expert and purchase of health education aids for an intensified program in Los Angeles. The Los Angeles Heart Association will act as executive and advisory committee to the new division. New officers of the California Heart Association chosen at its annual meeting in Del Monte, May 3, include Drs. Harold H. Rosenblum, San Francisco, president, Louis E. Martin, Los Angeles, vice president, and Charles E. Shepard, Palo Alto, secretary-treasurer.

### GEORGIA

**Vacancies in State Services**—The supervisor of examinations of the Georgia State Welfare Department announces competitive examinations for filling positions in the public assistance, crippled children and child welfare divisions. In the crippled children division the salary ranges are minimum \$1,800 and maximum \$2,280 for the position of medical social worker, orthopedic field nurse and physical therapy technician, for district orthopedic field nurse a minimum of \$1,920 and a maximum of \$2,400, for physical therapy consultant a minimum of \$2,400 and a maximum of \$2,880, orthopedic nursing consultant and medical social consultant begin at a minimum of \$2,700 and range to a maximum of \$3,180, medical director of the crippled children services begins at a minimum of \$4,200, with a maximum of \$5,400. In the child welfare group the positions of child welfare consultant and senior child welfare worker have a minimum of \$1,800 and a maximum of \$2,280, senior child welfare consultant and child welfare psychologist a minimum of \$2,400 and a maximum of \$2,520, senior child welfare consultant grade I a minimum of \$2,400 and a maximum of \$3,000, and child welfare worker a minimum of \$1,440 and a maximum of \$1,920. All these positions are open to competitive assembled examinations except the medical director of the crippled children services, which is an unassembled examination. The examinations are based on a rating of training and experience, a written test, and an oral interview. Each eligible who is appointed from the adequate register will be required to serve a probational period of six months as is the usual custom in civil service and merit system agencies. Georgia state residence is not required of an applicant in order to participate in these examinations.

### ILLINOIS

**State Medical Election**—Dr. George W. Post, associate professor of surgery, University of Illinois College of Medicine, Chicago, was chosen president-elect of the Illinois State Medical Society during its annual meeting in Springfield, May 21, and Dr. Edward H. Weld, Rockford, was installed as president. Drs. Hermon H. Cole, Springfield, and Charles O. Lane, West

Frankfort, were named vice presidents, and Dr. Harold M. Camp, Monmouth, was reelected secretary-treasurer. The next annual meeting will be in Chicago.

**Tuberculosis Control in Mental Hospitals**—Dr. Hubert S. Houston, Naperville, has been appointed supervisor of the tuberculosis control program in state mental institutions effective May 1, newspapers reported April 6. The appointment inaugurates a new program in state mental institutions. Dr. Houston will visit and supervise work in each institution, but each hospital will have its own physician to diagnose and treat each case. Dr. Houston graduated at the University of Illinois College of Medicine, Chicago, in 1928.

### CHICAGO

**The Ernest Irons Lecture**—Dr. Henry N. Harkins, Detroit, delivered the third annual Ernest Edward Irons Lecture of Kappa chapter of Nu Sigma Nu at the University of Chicago School of Medicine, April 23. His subject was "The Treatment of Burns in Wartime."

**Revocation of Fernel's License Upheld**—Circuit Judge John Prystalski, in dismissing a petition for a review of the findings, May 6, upheld the action of the state department of registration and education in revoking the license to practice medicine of Dr. Jean P. Fernel, newspapers reported. The license was revoked on charges of malpractice.

### IOWA

**Physicians Upheld in Distribution of Medical Relief Funds**—The right of ninety-three physicians who participated in the Linn County medical relief program last year to retain surplus funds amounting to \$1,900 was upheld by Attorney General Floyd Philbrick in an opinion received by County Attorney William W. Crissman, newspapers reported on May 3. The Linn County Medical Society on April 25 formally served a ninety day notice on the board of supervisors to cancel the contract with the county under which the physicians had been caring for the indigent sick, it was stated. Dissension over the contract arose in February, when Supervisor C. L. Beeson, Cedar Rapids, charged that the doctors had divided the \$1,900 left over from 1941 among themselves instead of returning it to the county. The physicians contended that the contract called for \$3,200 a month to be paid the society by the county and that the society had the right to use the money as it saw fit. They held that the surplus was available because the physicians had held down expenses and sacrificed fees throughout the year. The attorney general's opinion is said to have stated that the monthly payment of \$3,200 was made by Linn County to the physicians through the treasurer of the Linn County Medical Society, and "the sum thereby loses its character as public funds."

### KENTUCKY

**Public Health Activities in Louisville**—Dr. Hugh R. Leavell, health officer of Louisville, has been named full time director of the new Louisville and Jefferson County health department. Dr. Gracie R. Rowntree, assistant city health director, has been named assistant director of the unit. According to the state medical journal, Dr. John D. Trawick, Louisville, health officer of Jefferson County, has also been appointed assistant director of the city-county health department. The city-county board of health voted to change the name of the Louisville City Hospital to Louisville General Hospital.

### MARYLAND

**Dr. Thorn to Succeed Dr. Weiss at Harvard**—Dr. George W. Thorn, associate professor of medicine of Johns Hopkins University School of Medicine, Baltimore, has been appointed the Hersey professor of the theory and practice of physic at Harvard Medical School, Boston, and physician-in-chief of the Peter Bent Brigham Hospital. He will succeed the late Dr. Soma Weiss. Born in Buffalo in 1906, Dr. Thorn graduated at the University of Buffalo School of Medicine in 1929. He was a Rockefeller fellow in medicine at Harvard and Massachusetts General Hospital, 1934-1935, and at Johns Hopkins, 1936-1937. He served on the faculties of the University of Illinois and of Ohio State University College of Medicine, Columbus, going to Johns Hopkins in 1936. In 1932 he was one of the collaborators winning a gold medal, and was a member of the Committee on Scientific Exhibit of the American Medical Association for original investigative work on the development and use of a hormone from the adrenal cortex and its influence of presentation.

## MASSACHUSETTS

**Health Educator Dies**—Announcement is made of the recent death at the Baker Memorial Hospital, Boston, of J. Alice Andrews, Ph.D., aged 61, a native of Chesaning, Mich. Dr. Andrews studied at Michigan State Normal College, the University of Chicago, Harvard University and Clark University. He served as instructor in history and education, Manchester (Ind.) College, 1906-1907, head of the department of psychology and school hygiene State Normal School Worcester, Mass. 1908-1915, head of the department of psychology and child study, Boston Normal School 1915-1923 and since then as health lecturer on the staffs of several schools including Boston University and the Cleveland Institute of School Hygiene. He had written textbooks on health education. Since 1928 he had served as editor of the *School and Health Department of Hygiene*, the *Health Magazine*.

## MISSOURI

**The Terry Lecture**—Dr. George B. Wislocki, Parkman professor of anatomy, Harvard Medical School, Boston, delivered the second Robert J. Terry Lecture at the Washington University School of Medicine, Medical Alumni Foundation, St. Louis, April 22. His subject was 'The Primate Placenta, with Particular Reference to the Trophoblast.'

**New Cyclotron Now in Operation**—A cyclotron has been installed as a part of the Mallinckrodt Institute of Radiology, Washington University School of Medicine, St. Louis, producing a beam of deuterons of 250-350 microamperes with an energy of 12 million volts. The unit, which is located in an underground room on the campus about a mile away from the institute, was designed by Robert L. Thornton, Ph.D., in cooperation with Alexander S. Langsdorf Jr., Ph.D., and Harold Fulbright, A.B. The clinical application of the machine is under the direction of Dr. Sherwood Moore, director of the Mallinckrodt Institute. A clinic for treatment of diseases with radioactive isotopes has been established, and plans are under way to use the cyclotron in the treatment of malignant disease with neutrons. The entire seventh floor of the institute, originally designed for biologic laboratories, has been equipped for animal investigations utilizing radioactive isotopes as "tracers." A laboratory for investigation of the problem of phosphorylation has been established by Dr. Herman M. Kalchauer, research associate in radiology at the school of medicine. Another laboratory will be devoted to the fundamental problems of the use of radioactive isotopes in therapy under the direction of Dr. Louis H. Hempelmann, instructor in clinical medicine.

## NEW YORK

**Lecture in Public Health**—The Medical Society of the State of New York arranged for a special lecture on public health before the St. Lawrence County Medical Society in Ogdensburg, May 14. Dr. Haven Emerson, New York, gave the lecture on "The Private Physician's Place in Public Health."

**Personal**—Dr. William A. Brumfield Jr., Albany, has resigned as director of the division of syphilis control of the New York state department of health to accept a commission as major in the U. S. Army Medical Corps. Tentative assignment has been announced as venereal disease control officer in the fourth corps area with headquarters at Atlanta, Ga.

## New York City

**New Hospital Wing Dedicated**—The new \$375,000 wing of the Frances Schervier Home and Hospital for the aged and chronic sick in the Bronx was dedicated and formally opened recently. The new unit is part of the three million dollar hospital expansion program announced by Archbishop Spellman of New York more than two years ago. The hospital is built of red brick and Flemish bond. It was opened in 1938 and has private rooms and semiprivate wards. Nearly half the patients are cared for without charge and their average age is over 80.

**Professor du Vigneaud Named Chairman-Elect of Chemical Society**—Vincent du Vigneaud, Ph.D., professor and head of the department of biochemistry, Cornell University Medical School, was chosen chairman-elect of the New York section of the American Chemical Society at its annual meeting, May 8. The speakers at the meeting included John R. Dunning, Ph.D., associate professor of physics, Columbia University, on 'Production and Detection of Radioactive Isotopes';

and Glenn T. Seaborg, Ph.D., assistant professor of chemistry, University of California, "The Applications of Artificial Radioactivity to Chemistry, Biology and Medicine."

**Changes in Faculty at Columbia**—Dr. Vernon W. Lip-pard, assistant dean of Columbia University College of Physicians and Surgeons, has been appointed associate dean, it was announced on April 28. The following promotions have also been reported:

Dr. Alvan L. Barach to associate professor of clinical medicine  
Dr. Donovan J. McCune to associate professor of pediatrics  
Dr. Karl Meyer to associate professor of biochemistry  
Dr. David Seegal to associate professor of medicine  
Drs. Hartford Hallock and Leonidas Lantzonis to associate clinical professors of orthopedic surgery  
Dr. Andre Courmand to assistant professor of medicine  
Dr. Paul F. A. Hoefer to assistant professor of neurology  
Dr. Ruth A. Miller to assistant professor of anatomy  
Dr. Edith E. Sproul to assistant professor of pathology  
Dr. Raymond C. Truex to assistant professor of anatomy  
Dr. Sherwood L. Washburn to assistant professor of anatomy

The following were promoted to assistant clinical professors: Drs. Samuel C. Burchell, neurology, L. Beverley Chaney, neurology, Armistead C. Crump, medicine, Angus M. Frantz, neurology, Walter O. Klingman, neurology, and Hugh S. McKeown, ophthalmology.

## OHIO

**Alumni Banquet**—The alumni association of the University of Cincinnati will act as host to seventy-seven graduates of the college of medicine at a banquet, June 4. The occasion will be a joint meeting with the Cincinnati Academy of Medicine. Dr. Alexander Ashley Weech, recently appointed professor of pediatrics at the college of medicine, will be the principal speaker, on "War and Beyond the War, A Promise to Men of Medical Science."

**Changes in Health Personnel**—Dr. Elizabeth I. Workman, Columbus, has been named health commissioner of Delaware County, filling the unexpired term of Dr. George Frederick Moench, who went to the W. K. Kellogg Foundation in Michigan.—Dr. Albert J. Helm, London, health officer of Madison County, has been given jurisdiction over the unit in Union County under a recently adopted plan merging the two units.—Dr. Albert B. Headley, Cambridge, has been appointed health commissioner of Guernsey County, succeeding Dr. Marshall J. Thomas, Cambridge, resigned.—Dr. Clarence B. Rawers, Bergholz, has been appointed health commissioner of Jefferson County.

## OKLAHOMA

**Secretary for Twenty-Two Years**—Dr. Oscar E. Templin, Alva, was recently reelected secretary of the Woods County Medical Society for his twenty-second term. Dr. Templin graduated at Vanderbilt University School of Medicine, Nashville, Tenn., in 1905.

**Personal**—The Pittsburg County Medical Society recently presented a silver plaque to Dr. Frank J. Baum, marking his fiftieth anniversary in the practice of medicine. Dr. Tracey H. McCarley presented the plaque, and Dr. Leonard S. Willour acted as toastmaster. All are of McAlester.

**Society News**—A joint meeting of the Custer County Medical Society and the Southwestern Oklahoma Medical Association was addressed recently by Drs. Wann Langston, Oklahoma City, on 'Circulatory Emergencies: James William Finch, Hobart, Nausea and Vomiting Following Administration of Stilbestrol' and Paul B. Lingenfelter, Clinton, 'Foreign Bodies of Lung and Trachea'.—The Oklahoma County Medical Society was recently addressed in Oklahoma City by Dr. Frederick Redding Hood on 'Treatment of the De-compensated Heart'.—The Cherokee County Medical Society devoted its March meeting to a symposium on gynecologic endocrinology with Louis H. Ball, Ph.D., professor of biology, Northeastern Oklahoma State Teachers College, and Dr. Isadore Dyer, Tahlequah, as the speakers.

## PENNSYLVANIA

**Society News**—Dr. John S. McMurray, Washington, addressed the Washington County Medical Society, May 13, on 'Role of Endoscopy in General Medicine'.—Dr. Norman E. Freeman, Philadelphia, addressed the Harrisburg Academy of Medicine, May 19, on 'Peripheral Vascular Disease'.—Dr. Charles Howard Marey, Pittsburgh, discussed 'Chronic Nontuberculous Lung Conditions' before the Washington County Medical Society, April 8, in Washington.

## RHODE ISLAND

**State Medical Meeting in Providence**—The one hundred and thirty-first annual meeting of the Rhode Island Medical Society will be held in Providence, June 3-4, under the presidency of Dr. Frederic V. Hussey, Providence. Included among the speakers will be:

- Dr. Herman C. Pitts, Providence, New Phases of Cancer Research
- Dr. Robert H. Kennedy, New York, The Need for Fracture Knowledge in Wartime
- Dr. Robert A. Cooke, New York, The Practitioner and the Allergy Problem
- Dr. Timothy Leary, Boston, Arteriosclerosis, Its Causes
- Dr. Israel B. Cutts, Providence, Arthritis
- Dr. Arthur H. Ruggles, Providence, Psychiatric Aspects of Selective Service
- Dr. Edward D. Churchill, Boston, Military Aspects of Thoracic Surgery

Mr. Victor Coen, barrister and lecturer, London, England, will address the annual dinner Thursday evening on "Hitler, Napoleon and Philip II of Spain."

## TEXAS

**Continuation Courses**—Cardiology, dermatology, obstetrics and fractures will be the subjects of four courses to be given in Parkland Hospital, Dallas, June 22-24, under the auspices of the Dallas Southern Clinical Society. Additional information can be obtained from Dr. Charles H. Warren, secretary, Dallas Southern Clinical Society, 1133 Medical Arts Building, Dallas.

**Impostor Given Suspended Sentence**—Charles Peter Wisotsky, alias Wesotsky, alias Charles Peter West, alias Dr. David Walton Fell, who was convicted in U. S. District Court at Houston, May 1, of violation of the federal narcotic laws, was sentenced on May 9 to five years' imprisonment. The sentence was suspended on condition that Wisotsky immediately enter the armed forces of the United States. Wisotsky is not a graduate of any medical school and is not registered under the federal narcotic laws. He represented himself to be "Dr. David Walton Fell" and obtained a position as professor of pathology at the University of Texas School of Medicine, Galveston. He was given a staff appointment at the John Sealy Hospital, operated in connection with the medical school, holding the position from September 1940 to December 1941, when his identity was discovered and he was discharged. During the time he practiced medicine at the hospital, Wisotsky wrote several prescriptions calling for narcotic drugs. On Aug. 21, 1941, he wrote a prescription for a mental patient at the hospital calling for twelve ½ grain codeine sulfate tablets and another prescription for 1½ grains of digitalis, ½ gram of codeine sulfate and 50 grains of phenobarbital. The pharmacist in the dispensary refused to fill the latter prescription. In various credentials Wisotsky's claims are said to correspond with the educational background of a Dr. David Walton Fell listed in the British Medical Register.

## VIRGINIA

**Physician's Certificate Needed for School Enrolment**—The Montgomery County school board, Christiansburg, recently adopted resolutions requiring all children attending public schools next fall to present physicians' certificates before being enrolled; it is reported. Another provision requires all teachers, matrons and janitors to present certificates stating that they have been examined by physicians and are free from chest illnesses. These certificates must be presented every three years thereafter. The same group must also present certificates declaring that they are free from communicable diseases. These certificates must be renewed every twelve months.

**The McGuire Lectures**—Dr. John B. Youmans, associate professor of medicine, Vanderbilt University School of Medicine, Nashville, Tenn., delivered the annual Stuart McGuire lectures, May 7-8, at the Medical College of Virginia, Richmond, on "The Meaning of Nutrition" and "The Significance of Protein in the Diet." Other lectures delivered during this two day session, in cooperation with the department of clinical education of the Medical Society of Virginia, were:

- Roland J. Mann, Ph.D., Richmond, The Physiology of the Vitamins
- Dr. Henry B. Mulholland, Charlottesville, Nutrition Problems in Post-operative Patients
- Dr. Julian M. Ruffin, Durham, N. C., The Recognition of Mild or Early Vitamin Deficiencies
- Dr. Robert H. Courtney, Richmond, Ocular Manifestations in Deficiency Diseases
- Dr. Maxwell R. Berry Jr., Richmond, The Significance and Treatment of Iron Deficiency Anemia

## GENERAL

**College of Radiology**—The American College of Radiology will hold its annual meeting at the Chalfonte-Haddon Hall, Atlantic City, June 10, under the presidency of Dr. William Edward Chamberlain, Philadelphia.

**Meeting of Medical Section of Life Convention**—The thirty-second annual meeting of the medical section of the American Life Convention will be held at the Broadmoor, Colorado Springs, Colo., June 4-6, under the presidency of Mr. Alva J. McAndless, Fort Wayne, Ind. Included among the speakers will be:

- Dr. Peirce H. Long, Baltimore, The Importance of Sulfanilamide Therapy on the Future Underwriting of Risks
- Dr. Irvin Abell, Louisville, Peptic Ulcer—Surgical Conclusions Associated with Underwriting Conclusions
- Dr. Roy Lyman Sexton, Washington, D. C., Value of Minor Disturbances as a Clue to Gastrointestinal Disease
- Dr. Albert L. Johann, Des Moines, Iowa, The Medical Director's Role in Underwriting Selection of Life Insurance Risks
- Dr. Edwin G. Dewis, Newark, N. J., Field Examiner's Association with the Medical Director

**American Proctologic Society**—The forty-third annual meeting of the American Proctologic Society will be held at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 7-9, under the presidency of Dr. Frederick B. Campbell, Kansas City, Mo. Dr. Jerome M. Lynch, New York, will deliver the biennial Joseph M. Matthews Oration. Speakers include:

- Dr. Cornelius P. Rhoads, New York, The Chemical Aspects of Cancer
- Dr. George E. Binkley, New York, Pre and Postoperative Care of Patients with Rectal Cancer, with Special Reference to Liver Damage
- Dr. George Johnson Hamilton, New York, Aviation and the Proctologist
- Dr. Vernon G. Jeurink, Denver, The Role of Surgery in the Treatment of Idiopathic Ulcerative Colitis
- Dr. Wayne W. Flora, Chicago, Urinary Retention Following Anorectal Operations
- Dr. Frank C. Yeomans, New York, Granulomata of the Rectum Specific and Nonspecific

**Association for Research in Ophthalmology**—The meeting of the Association for Research in Ophthalmology will be held at the Marlborough-Blenheim Hotel, Atlantic City, N. J., June 9. Included among the speakers will be:

- Dr. Manuel U. Troncoso, New York, The Intracranial Vascular Plexus and Its Relations to the Aqueous Outflow
- Dr. Kenneth C. Swan and Norman G. White, M.S., Iowa City, Corneal Permeability Factors Affecting Penetration of Drugs into the Cornea
- Dr. Theodore L. Terry, Boston, Fibroblastic Overgrowth of Persistent Tunica Vascularis Lenticis in Infants Born Prematurely. Studies in Development and Involution of the Hyaloid Artery and Tunica Vascularis Lenticis
- Dr. Erich Sachs, Detroit, Some Observations and Experimental Studies on the Physiology of the Ciliary Muscle
- Dr. Ludwig von Sallmann, New York, Sulfadiazine Iontophoresis in the Treatment of Pyocyanous Infection of the Rabbit Cornea
- Dr. Charles W. Ascher, Cincinnati, The Aqueous Viscosity: Physiologic Importance of the Visible Elimination of the Intracocular Fluid

**Dedication of Painting "The Dawn of Abdominal Surgery"**—Special exercises will be held in the Rose Room of the Traymore Hotel, Atlantic City, N. J., June 8, to unveil and dedicate the new painting of Dean Cornwell on "The Dawn of Abdominal Surgery." The dedicatory address will be given by Col. Fred W. Rankin, M. C., U. S. Army, Lexington, Ky., President-Elect of the American Medical Association. The painting is the fourth in a series which will take between ten and fifteen years to complete, one to be done a year. The first three were "Beaumont and St. Martin," "Osler at Old Blockley," and "Pioneers of American Medicine." The third in the group shows Major Walter Reed and Dr. Carlos Finlay with Major General Leonard Wood, Dr. Jesse W. Lazear, Dr. James Carroll and Dr. Aristides Agramonte, and John R. Kissinger, first volunteer soldier to be inoculated in the second set of yellow fever experiments. The series is being financed by John H. Wyeth and Brother, Inc.

**Live Mouse Found on Airplane Arriving at Miami**—The May 8 issue of *Public Health Reports* gives what is believed to be the first instance in this country of a live mouse found on an airplane arriving at quarantine. Surg. Gilbert I. Dunnahoo, medical officer in charge of the U. S. Quarantine Station, Miami, stated that on April 16 a live mouse was recovered from the galley of a plane on inspection after arrival at Miami from San Juan, P. R. Considering the increase in the size of transport planes, the carrying of food stuffs and the ingenuity of rats in seeking food supplies, avoiding man's devices for destroying them, the possibility of rats boarding airplanes is not remote. Should an infected rat harboring a species of flea capable of transmitting plague succeed in stowing away in an airplane, the danger of infection developing also would not be remote. The first mouse on board a transport plane at its destination emphasizes the necessity for greater vigilance on the part of airplane companies and quarantine officers in combating danger.

**Broncho-Esophagological Meeting**—The twenty-fifth annual meeting of the American Broncho-Esophagological Association will be held at the Hotel Dennis, Atlantic City, N J, June 8-9, under the presidency of Dr W Likely Simpson, Memphis, Tenn. Among the speakers will be

- Drs Louis H Clerf and Carl J Bucher Philadelphia Adenoma (Mixed Tumor of the Bronchus)  
Dr Paul H Helinger Chicago Kodachrome Visualization of the Physiology and Pathology of the Tracheobronchial Tree  
Drs Emil L Van Loon Philadelphia and Sidney Diamond Woodlyn Pa Foreign Bodies in the Gastrointestinal Tract  
Drs Sidney S Cellis and Luther Emmett Holt Jr, Baltimore The Prophylaxis of Lye Strictures of the Esophagus  
Drs Fletcher D Woodward and William W Waddell Jr Charlottesville Va Bronchoscopy in the Newborn  
Dr Kenneth A Phelps Minneapolis Some Further Observations on Tuberculous Tracheobronchitis

A dinner to honor the founders and charter members of the original association, the Clinical Association of American Peroral Endoscopists, will be held at the Hotel Dennis Tuesday evening June 9, at 7 o'clock. Dr Ellen I Patterson, Pittsburgh, will give an address on the history of the association.

**Association for the Study of Allergy**—The twentieth annual meeting of the American Association for the Study of Allergy will be held at the Chalfonte-Haddon Hall, Atlantic City, N J, June 8-9, under the presidency of Dr Milton B Cohen, Cleveland, whose address will be entitled 'The Basic Relationship of Allergy and Immunity'. Among the speakers will be

- Mr Oren C Durham, North Chicago Ill Kochia Scorpria as a Factor in Inhalant Allergy  
Dr Marion T David on Birmingham Ala The Source of the Activity of House Dust  
Drs George F Harsh San Diego Calif and Harry L Huber Chicago Studies of Tryptic and Pepsic Digestion of Extracts of Giant Rag weed Pollen  
Dr Stanley Cohen New Orleans Ascorbic Acid Metabolism in Asthma  
Drs James Alexander Clarke Jr and Charles M Hanna Philadelphia The Incidence of Nontuberculous Respiratory Disease in Various Sections of the Population  
Drs John Warrick, Thoma Cleveland and Meryl M Fenton Detroit Fatalities and Constitutional Reactions Following Use of Pontocaine

There will be a round table discussion Tuesday on 'The Immunology of Allergy' with Dr Milton Cohen, Dr Paul R Cannon, Chicago, and Jacques J Bronfenbrenner, DPH, St Louis.

**American Therapeutic Society**—The forty-third annual meeting of the American Therapeutic Society will be held at the Hotel Traymore Atlantic City, N J, June 5-6, under the presidency of Dr Harold S Davidson, Atlantic City. Among the speakers will be

- Drs Michael G Wohl and Harold F Robertson Philadelphia, Bromide Intoxication  
Drs Ernest A Spiegel Philadelphia and Norman P Scala Washington, D C The Importance of Nystagmus in Differential Diagnosis  
Dr Charles H deT Shivers Atlantic City The Medical Findings in Benign Prostatic Hyperplasia A New Method of Grouping Cases for Operation  
Drs Nathan S Davis III and Eduard F Poser Chicago Ascorbic Acid in the Treatment of Essential Hypertension—Preliminary Report  
Dr David Salkin Hopewell W Va The Natural History of Tuberculous Tracheobronchitis  
Dr George P Viley Philadelphia Ultraviolet Blood Irradiation Therapy  
Dr Robert A Kilduffe Atlantic City Transfusion as a Therapeutic Measure  
Drs Harry E Ungerleider and Richard S Gubner New York Extra systoles and the Mechanism of Palpitation

The annual banquet will be held on Saturday at the Hotel Traymore at 8 o'clock. The principal speaker will be Dr Reginald Fitz, Boston, on 'Something Curious in the Medical Line'.

**Heart Association Meeting**—The eighteenth scientific sessions of the American Heart Association will be held at the Chalfonte-Haddon Hall, Atlantic City, N J, June 5-6, under the presidency of Dr Paul D White, Boston. Among the speakers will be

- Dr William P Thompson Los Angeles The Electrocardiogram in the Hyperventilation Syndrome  
Drs Edward A Edwards and John E Edwards Boston The Venous Valves in Thromboangitis Obliterans  
Dr James Ross Veil Washington D C Thrombosis of the Subclavian and Axillary Vein  
Dr Abram Wilbur Durrer New York The Present Concept of Scleroderma and Its Allied Diseases  
Dr Herbert Charles William Coldring and Homer W Smith New York The Reduction of Blood Pressure Associated with the Pyrogenic Reaction in Hypertensive Subjects  
Drs Hilbert A Kanger and Stanley E Bradley New York Systemic and Renal Circulatory Changes Following Administration of Paredrinol  
Drs Willis F Evans and Harold J Stewart New York The Effect of Cigarette Smoking on the Peripheral Blood Flow

The annual dinner will be held Friday, June 5 at 7:15 p m. Dr White will be the principal speaker on Pioneer Days of the Discovery of Heart Disease. Dr Pedro Cosío, Buenos

Aires, Argentina, will deliver the Lewis A Conner Lecture on "Heart Disease in the Argentine" and Major Harry G Armstrong, M C, U S Army, Randolph Field, Texas, the George Brown Memorial Lecture on "The Effect of Flight on the Cardiovascular System".

**American Radium Society Meeting**—The twenty-seventh annual meeting of the American Radium Society will be held at the Chalfonte-Haddon Hall, Atlantic City, N J, June 8-9, under the presidency of Dr Hayes E Martin, New York. Among the speakers will be

- Dr Hoke Wammoth Philadelphia Fractures of the Rib Cage Following Interstitial Radium Therapy for Cancer of the Breast  
Dr Daniel P Slaughter New York Radiation Osteitis and Fractures Following Irradiation with Report of Five Cases of Fractured Clavicle  
Dr John E Teach New York The Effect of X-Ray Therapy on the Heart A Clinical Study  
Drs Jerome A Urban and William L Watson New York Milion Volt Therapy for Intrathoracic Neoplasms  
Drs James F Nolan and Axel A Arneson St Louis Introducer for Inserting Multiple Capsules of Radium in the Uterus for the Treatment of Corpus Cancer  
Andrew J Ackerman DDS New York Facial and Oral Prostheses  
Drs William P Healy and Gray T Twombly New York The Effect of Increasing the Dose of Roentgen Therapy to the Parametria on the Rate of Cure in Treatment of Cancer of the Cervix  
Mr John E Rose Baltimore A Remote Controlled Radon Plant and Automatic Measuring Apparatus  
Leon F Curtiss PhD Washington D C, Protection of Radium Under War Conditions  
Dr Ignacio Gonzalez Guzman Mexico City, Mexico The Centrosomes in Some Neoplastic Growths

The annual banquet will be held at the Chalfonte-Haddon Hall on Monday evening, June 8. Dr Healy will deliver the Janeway Lecture, June 8, on "The Role of the Gynecologist in the Field of Cancer".

**Association for the Study of Internal Secretions**—The twenty-sixth annual meeting of the Association for the Study of Internal Secretions will be held at the Hotel Traymore, Atlantic City, N J, June 8-9, under the presidency of Edgar Allen, PhD, New Haven, Conn., whose address will be entitled "A Picture Album of Tumors in Experimental Animals Following Estrogenic Treatment". Included among the speakers will be

- Drs Byron D Bowen, George F Koepf, Grosvenor W Bissell and Donald W Hall Buffalo Metabolic Changes in Coexisting Diabetes Mellitus and Addison's Disease  
Drs I Arthur Minsky, Norton Nelson and Samuel Elgart, Cincinnati Species Difference in Diabetes Mellitus  
John W Everett PhD Durham N C Further Studies of the Relationship of Progesterone to the Induction of Ovulation in the Persistent Estrous Rat  
Dr Charles H Lawrence and Nicholas T Werthessen, Boston The Treatment of Acne with Orally Administered Estrogens  
Dr Harry A Gusman Cleveland and Dr Maximilian A Goldzieher New York Synergism Between Pituitary Extracts and Chorionic Gonadotropin  
Warren O Nelson PhD and Eugene Cutuly PhD Detroit Gonadotropic Factors Influencing the Function of the Corpus Luteum  
Drs Willard O Thompson, Norris J Heekel and Richard P Morris Chicago Endocrine Regulation of Growth  
Drs Solomon C Freed, Walter M Eismann and Jacob P Greenhill Chicago Therapeutic Use of Diethylstilbestrol Dipalmitate

The annual dinner of the association will be held at 7 o'clock on Monday evening, June 8, at the Hotel Traymore.

**American Urological Meeting**—The thirty-ninth annual meeting of the American Urological Association will be held at the Waldorf-Astoria Hotel, New York, June 1-4, under the presidency of Dr Oswald S Lowsley, New York, whose address will be entitled "Urology in a Changing World". One session will be offered by the following:

- Drs Carlos Lobo Onell and Ignacio Diaz Munoz Santiago Chile Results of Treatment of Diffuse Glomerulonephritis by Surgery  
Alfonso Davalos Ecuador Experimental Production of Stones in the Bladder in Rabbits  
Dr Armando Trabucco Buenos Aires Argentina Kidney Injuries Clinical and Anatomopathological Results  
Dr Ricardo Machin Havana Cuba Ureteral Surgery  
William Vilme Port-au-Prince Haiti Avivement and Suture of Vesical Neck in Some Cases of Incontinence of Urine in Women Due to Vesicocervicovaginal Fistula with Complete Destruction of the Urethra  
Dr Eduardo Castro Mexico City Urinary Extravasation  
Dr Miguel A Llano Rosario Argentina Vesical Diverticula  
Dr Leopoldo E Lopez Caracas Venezuela The Incidence of Genitourinary Tuberculosis in Venezuela  
Dr Miguel Antonio Rueda Bogota Colombia Cancer of the Testicle  
Dr Hector Diaz Castro Montevideo Uruguay Traumatic Infection of the Testicle (Intra and Extravaginal) with Sarcoma of the Prostate in a Child  
Ferdinand Gonzales Yucatan Mexico Serum Lectinography  
Dr Waldemar F Cecatti Santiago Genitourinary Lesions in Vegetal Lemnigranulema

Dr Herbert M Evans Berkeley Calif will deliver the Ramon Gutierrez Lecture June 3 on Testicular Neoplasms and Urinary Gonadotropic Hormone. There will also be a

diplomatic luncheon on Thursday, June 4, with the following speakers Bishop John F. O'Hara, military ordinariate, United States, dean of South American medical men present, representatives of ambassadors of Latin American countries, dean of New York Consuls General, Mr. Nelson Rockefeller or a representative of the Division of Cultural Relations of the Department of State, and closing remarks by Dr. Lowsley Dr. Elmer Hess, Erie, Pa., will be the toastmaster.

### CANADA

**Canadian Medical Association Meeting**—The seventy-third annual meeting of the Canadian Medical Association will be held in Jasper Park, Alta., June 15-19, under the presidency of Dr. Gordon S. Fahrni, Winnipeg, Man. Headquarters will be at the Jasper Park Lodge. Dr. Paul A. O'Leary, Rochester, Minn., will present two papers, "The Treatment of Psoriasis" and "Dermatosclerose." Among other speakers on the program will be

Dr. Carleton B. Pearce, Montreal, Quebec, Recent Improvements in the X-Ray Diagnosis of Nontuberculous Pulmonary Diseases by Means of Bronchography

Dr. John F. Burgess, Montreal, Vitamins in Dermatology

Dr. Donald E. H. Cleveland, Vancouver, B. C., The Treatment of Pruritus Ani

Dr. Andrew M. Davidson, Winnipeg, Manitoba, Recurring Vesicular Eruptions of the Hands

Dr. George S. Williamson, Ottawa, Ontario, Sarcoidosis Systemic and Cutaneous Manifestations

Dr. Walter Ford Connell, Kingston, Ontario, Digitalis, Its Uses and Misuses

Dr. George E. Tremble, Montreal, Headache of Nasal Origin

Dr. Arthur L. Yates, Halifax, N. S., Sudden Deafness

Dr. Robert I. Harris, Toronto, Ontario, Spondylolisthesis

Dr. Morley A. R. Young, Lamont, Alberta, Present Status of Duodenal Ulcer Surgery

The program will also include the following series of round table conferences

Dr. Frederick F. Tisdall, Toronto, The Use and Abuse of Vitamins  
Dr. David C. Aikenhead, Winnipeg, Problems of Respiration and Anoxemia

Dr. Donald H. Williams, Vancouver, Syphilis

Dr. Harold Orr, Edmonton, Alberta, Cutaneous Cancer

Dr. James D. Adamson, Winnipeg, Recognition and Treatment of Poliomyelitis in General Practice

Dr. Duncan Graham, Toronto, The Selection of Sulfanilamide and Related Compounds in Medical Treatment

Dr. Rosslyn B. Mitchell, Winnipeg, Rational Endocrine Therapy in Obstetrics and Gynecology

Dr. John R. Vant, Edmonton, The Treatment of Prolapse

Dr. Robert Graham Hueckell, Edmonton, Pediatric Prevention of Future Foot Disorders

Dr. Alfred Howard Spohn, Vancouver, Adolescent Problems

Dr. Bede J. M. Harrison, Vancouver, Radiotherapy of Nonmalignant Diseases

Dr. W. Herbert McGuffin, Calgary, Presentation and Discussion of Interesting Films

Dr. Charles W. Burns, Winnipeg, Principles and Practice in Wound Treatment

Dr. Roscoe R. Graham, Toronto, Problems in Bile Tract Surgery

Dr. Frank S. Patch, Montreal, Urinary Complications Following Rectal Surgery

### FOREIGN

**Public Health Under Hitler's Rule**—Diphtheria is rapidly spreading in West Brabant, according to the *Nationale Dagblad*, Utrecht, February 6, several schools have been closed and 5 children have died. In Etten about 2 new cases a day were reported.

According to *Limbursch Dagblad*, Heerlen, February 2, there is an increasing shortage of medicines. Doctors have been asked to be as economical as possible and to try to get results by recommending diets, bandages are said to be very scarce.

According to *Magyar Nemzet*, February 14, Dr. Istvan Gaertner, chief medical officer, at a meeting of the Hajdu County Council, reported that 4 cases of typhus had occurred in a Gypsy settlement in the district of Kaba.

*Nova Hrvatska*, Zagreb, of February 14 reported that it had been necessary to evacuate the military hospital at Sarajevo, and a temporary one hundred and fifty bed hospital had been opened in the town school.

An epidemic of typhoid in Trikkala was reported by the Berlin correspondent of the *Svenska Dagbladet*, Stockholm, and its spread was feared, as the people were said to be starving and therefore more liable to infection than under normal conditions.

According to the *Hamburger Fremdenblatt*, March 7, German typhus research workers have found a rapid method of diagnosing typhus bacilli in the blood of patients and are producing antityphus vaccine by a method which makes it possible to produce it in any required quantity. The Behring works are expected to build a laboratory in Lwow to produce the vaccine.

The number of obituary notices in the German press of members of the German armed forces who have died as the

result of "malicious illness" in the east or from a "serious illness contracted in the east" in a reserve hospital at home has been increasing. Among the victims of such illnesses are Oberstleutnant Dr. Herbert von Spies, aged 54 (*Munchen Neueste Nachrichten*, March 5), Waldemar Herbst, aged 37 (*ibid*, March 7), Lieut. Gen. Gerhard Lindner, aged 37 (*Beobachter*, February 24), SA Oberscharfuhrer/Unteroffizier P. G. Erich Schwarz, aged 37 (*ibid*, March 6), SA Sturmfuhrer P. G. Werner Gerlach, aged 31 (*ibid*, March 10), Staff Captain Karl Heinrich Thele, aged 46 (*Deutsche Allgemeine Zeitung*, March 8), Lieut. Col. Hans Garcke, holder of the Iron Cross from the last war (*ibid*, March 7).

Radio Hilversum, March 14, reports the departure of the Dutch Ambulance Corps to the eastern front from the railway station in the Hague. The party of four specialists, two surgeons, an oculist, a throat and ear specialist and numerous general practitioners went off decked with flowers before a gathering of authorities. They were to go first to Germany for military training. Their train carried beds, surgical instruments, operating equipment and x-ray apparatus. The Ambulance Corps is equipped to set up a motorized hospital on the eastern front.

The Robert Koch Institute for Infectious Diseases was taken over by the reich on April 1, according to NDZ, March 30, and given the new name Robert Koch Institute—Reichsanstalt zur Bekämpfung der übertragbaren Krankheiten. The work of the institute has been extended since the outbreak of the war and now is concentrated on epidemics threatening from the eastern frontier. The various departments are concerned with research in virus diseases, the treatment of disease with synthetic remedies, the discovery of new disinfectants, with immunization against smallpox, diphtheria and rabies, and with the study of tropical diseases.

According to *Nova Hrvatska*, Zagreb, March 27, there has been an epidemic of typhus near Ljubuski in Herzegovina. The minister of public health spoke to the "sabor" on measures to prevent epidemics. A trainload of anti-typhus equipment was sent from Sarajevo to Bosnia and special places with baths and disinfecting equipment were constructed at Zemun, Hrvatska Mitrovica, Vinkovci, Brod, Nova Gradiska and Zagreb. New hospitals have been erected at Jajce, Bugojno, Bosut, Zvornik and Bjeljina.

On April 10 the largest and most modern hospital in the country was opened in the Zagreb suburb of Rebro, according to the *Neue Tag*, Prague, March 24, on the site of the old synagogue, which has been destroyed, a state building is being erected which will be used as an art gallery.

According to *Le Matin* in occupied France, the night medical taxi service, reserved for doctors, was resumed on March 1, after having been temporarily suspended. A day service of medical taxis was begun also, one taxi daily per hospital, stationed at the Hotel-Dieu, Necker and Marmottan.

A dispatch from Athens, Greece, through German source, reported on May 19 that all theaters, schools and concert halls had been closed to protect the population from the extension of typhus, a few cases of which had been reported.

### CORRECTIONS

**Kentucky Psychiatrists Elect Officers**—Dr. Abraham Wikler, Lexington, Ky., writes that he was not elected vice president of the Kentucky Psychiatric Association as reported in THE JOURNAL, May 9, page 196. He was elected to membership in the group. The source of the news item in THE JOURNAL was the *Kentucky Medical Journal*, March, page 115.

**Dr. Frank Cregor Retires at Indiana**—THE JOURNAL, April 18, page 1379, announced that Dr. Frank M. Gastman, Indianapolis, had been named head of the department of dermatology and syphilology at the Indiana University Medical Center to succeed Dr. Paul Cregor. This announcement was based on an official release from the university. A letter from the news bureau of the university now reports that the retiring member of the faculty is Dr. Frank W. Cregor, Indianapolis.

**Immunization of Infants—Toxoid Instead of Toxin**—In the current medical literature department of THE JOURNAL, May 9, page 224, in the abstract of Dr. J. H. Lapin's article in the *American Journal of Diseases of Children*, in the fourth line from the top in the second column the word "antitoxin" should have been "toxoid." Dr. Lapin's article is the whole point of active immunization against tetanus, and the use of toxoid to avoid the unfortunate reactions of antitoxin.

April 11 1942

#### National Health Under War Conditions

In war time there are reasons for the Ministry of Health not presenting the usual annual reports. Instead a report has been presented for the two years ended March 31, 1941, which consist of five months of uneasy preparation for war and nineteen months of war itself. The health of a nation is one of the decisive factors in war, and a desire has been expressed in more quarters than one for fuller information on the public health. In the last annual report, for the year ended March 31, 1939, the minister of health described the preceding twenty years as "a period during which unexampled efforts have been devoted to the development of public health and welfare services. For over two years now these efforts have had to be diverted to special war services. With rare but notable exceptions the work on normal services has perforce been limited to maintenance. But it is satisfactory that in this third winter of the war the health of the people remains good. Many new problems have arisen from redistribution of the population resulting from evacuation in consequence of air raids and industrial war effort. The Red Cross Society, Women's Voluntary Services, the National Council of Social Service, the Salvation Army and other organizations have given great help to the authorities in dealing with health and welfare problems arising from the war."

When war broke out increased nervous strain was expected to make itself felt in various ways. Progressive food rationing, longer hours of work and the interference of the blackout with ventilation raised apprehensions. When the attack was turned on this country, outbreaks of infectious disease were anticipated from the crowding of people into shelters or the damage to water mains and sewers. But the national health remained surprisingly good. A survey of communicable diseases during the war follows.

#### CEREBROSPINAL FEVER

A disturbing feature was a sharp rise in the incidence of cerebrospinal fever but the fatality rate was the lowest known. The increased incidence may have been due to war time crowded conditions promoting droplet infection. The number of cases notified in England and Wales during 1940 was 12,771 with 2,584 deaths. In 1941 the incidence increased again but less steeply, in the March quarter there were 4,329 cases with 891 deaths.

#### DIPHTHERIA AND SCARLET FEVER

War time conditions did not increase the prevalence of these diseases, there were fewer cases of diphtheria in 1940 than in 1939. This may have been due to large scale immunization of the child population between the ages of 1 and 15 because of the increased risks of spread. Abundant facilities for immunization were provided and parents were instructed in its value.

#### TYPHOID AND PARATYPHOID

In 1939 the deaths for typhoid and paratyphoid fell to the unprecedentedly low figure of 112. In 1940 there was a rise to 135, but this figure was below the two previous records. The rise in incidence was due to the milder form of paratyphoid. In December 1940 because of the risk of damage to water systems by air raids free immunization against the typhoid group of organisms was offered to the public.

#### TUBERCULOSIS

In 1939 the number of deaths in England and Wales from respiratory tuberculosis for an estimated population of 41,460,000 was 22,199 and in 1940 for a population that had not varied

greatly, 23,660. The crude death rate per million thus rose from 535 to 571. The increase was most noticeable in young women between the ages of 15 and 25. History shows that war favors the spread of tuberculosis.

#### VENEREAL DISEASES

The incidence of venereal disease is best judged by the figures for syphilis, as the use of sulfonamide derivatives makes the figures for gonorrhea less reliable. New infections with syphilis declined steadily by over 46 per cent between 1931 and 1939. The decline stopped in 1940, when the number of patients with new infections seen for the first time at treatment centers in England and Wales rose sharply to 5,611, i. e. by 125 per cent. If infections in the fighting services are added, the increase rises to 23 per cent, a figure higher than that for 1935 and subsequent years and in accordance with past experience of war. The wider prevalence is being combated in every way.

#### MATERNAL AND INFANT MORTALITY

The fall in maternal mortality which began in 1934 has continued and 261 per thousand births in 1940 is the lowest on record. Factors in the reduction are the recent advances in the treatment of puerperal sepsis and improvement in domiciliary midwifery. The fall in infant mortality has suffered a check. In 1939 it fell to 50 per thousand live births, but in 1940 it rose to 56. Yet these figures show the great improvements of maternity and child welfare services between the two great wars. In the second year of the war of 1914-1918 the infant mortality was 110.

#### AMERICAN HELP

The report expresses gratitude for the flow of gifts of equipment and supplies, in which the United States has been predominant. Help has been given in the provision of residential nurseries. Harvard University in association with the American Red Cross contributed a field hospital constructed in America and fully equipped and staffed. It is now functioning for the investigation and treatment of outbreaks of communicable diseases. The American Red Cross, the British War Relief Association of New York and Bundles for Britain have been the main other channels through which contributions from the United States have reached this country.

#### Institute for Blinded Warriors Open to All Allies

St. Dunstan's, known throughout the British empire for its work in helping the victims of war to victory over blindness," has now opened its doors to all the allies. It was founded after the last great war for the training, settlement and after-care of men blinded in the fighting. The occupations taught are massage, typewriting, shorthand, telephony, poultry farming, joinery, basket making, boot repairing, mat making, netting and wool rug making. Weekly allowances are paid for the children of the blinded men up to the age of 16 who do not receive state allowances.

At a meeting of representatives of the allied powers Sir Ian Frazer, superintendent of St. Dunstan's assured them that it would be as freely open to their peoples as to British citizens. Mr. Harold Shantz of the American embassy expressed the warm appreciation of the allied nations for the offer. The work of St. Dunstan's was well known in the United States which would gladly cooperate in caring for any British service men blinded in the war who reached there. Sir Ian Frazer, who himself is an example of how St. Dunstan's conquers blindness, gave the allied representatives an account illustrated by films of how it conquers blindness. He mentioned that they had a Polish soldier blinded at Narvik, a Polish officer who lost his sight through hardships endured during his escape across many European countries to Britain, a sailor of the French navy blinded while his ship was evacuating French and British soldiers from Dunkirk, a French soldier evacuated from Dan-

kirk in a British hospital ship and a Dutch dispatch rider. In the present war 122 persons had been through St. Dunstan's as the result of eye damage. About half recovered some useful sight. Many totally blinded had successfully returned to industrial work in the national war effort.

#### Famine in Greece

A memorandum issued by the Greek government states that according to the Red Cross about forty thousand persons, including a high proportion of children in Athens and the Piraeus, died of famine and diseases caused by malnutrition between Oct. 1, 1941 and Jan. 26, 1942. The quality of such food as is available is low through lack of fats. Each daily ration contained only 500 calories against the 2,500 issued by feeding centers in the previous winter. The situation in other cities, Salonika, Patras and Volo for example, is equally tragic and it is believed that nine hundred deaths occur daily. In the islands the situation is disastrous, notably in Chios and Syra, where the inhabitants telegraphed to Athens "Send wheat or coffins." For these horrors, which take their place besides those of Poland and Yugoslavia, the Germans are responsible. The memorandum charges them with a deliberate attempt to destroy the Greeks.

#### BUENOS AIRES

(From Our Regular Correspondent)

March 28, 1942

#### Heart Disease in Children

Drs. J. M. Macera y Araya and Alberto P. Ruchelli for several years have given attention to heart disease in children in Argentina. They recently published a book entitled *Las cardiopatías en nuestro medio escolar*. The classification of patients is the same as the classification followed by the *American Heart Journal* with some modifications. For the selection of an occupation the children in the first group are orientated as if they were normal, although with some slight restrictions unless the disease progresses and the patients may be considered as fitted for the second group. For children in the second group, occupations which do not demand violent efforts are to be selected. Children in the third group should follow occupations which can be carried on slowly and in which the patient can work sitting down and standing up for alternate periods. Occupations for children in the fourth group should be those which can be carried on slowly, without any effort, and in which the patient can work while sitting down at all times. Children in the fifth and last group of the classification cannot work. In their book the authors describe twenty-two psychotechnical tests. The following are investigated: (1) sight, hearing and visual differentiation of colors, (2) physical capacity, (3) mentality, (4) technical aptitude and (5) abstract intelligence. The psychotechnical examination takes two hours for each patient. The authors selected the proper occupations for forty-six children with heart diseases.

#### The Faculty of Medicine of La Plata

The Faculty of Medicine of La Plata was established in 1934. The number of students in the freshman class at the school is limited to one hundred and twenty-five. There are thirty-four chairs with regular professors and twenty-seven substitutes and assistant professors. Dr. Orestes E. Adorni is dean of the faculty. The following are professors: Drs. Victorio Monteverde, professor of clinical obstetrics, Carlos M. Albizzati, professor of biologic chemistry, F. L. Soler of physiology, Manuel Cieza Rodriguez of clinical surgery, Rogelio Carratala of toxicology, Francisco R. D'Ovidio of pathology and clinical course of tuberculosis, Egidio S. Mazzei and Federico S. Lozano of clinical medicine, Carlos Ruera of medical pathology, Enrique C. Baldassarre, assistant professor of pharmacology, and Dionisio Echave, free teacher of biologic chemistry. Because of the proximity of La Plata to Buenos Aires, many

of the teachers of the Faculty of Medicine of the University of Buenos Aires are also professors at the Faculty of Medicine of the University of La Plata. The *Anales de la Facultad de Ciencias Medicas de La Plata* is the official organ of the Faculty of Medicine of La Plata. It contains articles on work carried on by the authors at the laboratories or clinics of the faculty. The seventh volume, containing four hundred and thirty-eight pages, recently appeared.

#### Hemorrhagic Pleurisy in Cirrhosis of Liver

Dr. Christian wrote an article entitled *Bloody Pleural Fluid, an Unusual Complication of Cirrhosis of the Liver* for the *Golden Book of Dr. Joseph Hersey Pratt* in 1937. The article was then published in the *Annals of Internal Medicine* (10:162) [May] 1937. Recently Drs. Mariano R. Castex, Egidio S. Mazzei and Jorge Remolar reported their observations in hemorrhagic pleurisy in patients with cirrhosis of the liver, in *Prensa Medica Argentina* (1941, 28, number 33). They found that hemorrhagic pleurisy alone or in association with hemorrhagic ascites may complicate cirrhosis of the liver. They performed pleuroscopy in cases of hemorrhagic pleurisy and laparoscopy in hemorrhagic ascites complicating cirrhosis of the liver. The authors found that hemorrhagic pleurisy and hemorrhagic ascites in patients with cirrhosis of the liver is due to hematogenous tuberculosis.

#### Spectroscopic Analysis of Saliva for Alkaloids

Drs. Ramon G. Loyarte and Jacinto Placeres recently published an article in the *Publicaciones de la Facultad de Ciencias Fisicomatematicas* of the University of La Plata. They direct attention to the difficulties of identifying alkaloids in the saliva of "doped" animals, especially race horses, and describe a method by which cocaine, morphine, caffeine and strychnine can be determined in the saliva by means of the ultraviolet absorption spectrum. The drug is identified in saliva by this method, even if the animals had been given only small stimulating doses. The authors experimented with race horses. Two hours after the injection the horses were made to run 1,000 or 1,600 meters, after which saliva was taken from the animals' mouths for analysis. They conclude that the spectrographic method is reliable for identification of the alkaloids mentioned.

### Marriages

- ROBERT A. RYAN JR., Mountain Grove, Mo., to Miss Frances Isabel Sells of Ottumwa, Iowa, in Evanston, Ill., March 23.  
THOMAS WILLIAMS BAKER, Charlotte, N. C., to Miss Margaret Mesley Lunsford of Durham in March.  
CLYDE ERWIN CHANEY, Eastland, Texas, to Miss Justice Ann Reedy at Memphis, Tenn., March 24.  
WILLIAM V. KNOLL, Boston, to Miss Blanche Ellis Stewart of Colorado Springs, Colo., Nov. 30, 1941.  
JAMES BAKER TWYMAN, Charlottesville, Va., to Miss Bertha Darios of Portland, Ore., March 27.  
JAMES GARNETT BRUCE JR., Watts Bar Dam, Tenn., to Miss Janet Floyd of Chattanooga, March 4.  
JOSEPH THOMAS WYCHE, Hallsboro, N. C., to Miss Elizabeth Calder at Charlotte in March.  
JOHN RILEY BLACK JR. to Miss Alma Jane Miller, to of Whitesville, N. C., March 26.  
JOHN PENNINGTON BOND, Baltimore, to Miss Helen P. F. of Albemarle, N. C., March 14.  
THOMAS G. LUPO, Oteen, N. C., to Miss Merdie Johnson of Carrollton, Ala., in March.  
JESSE T. SCHWIDDE, Iowa City, to Miss Catherine Ma, F. at Boone, Iowa, February 28.  
ROBERT C. LAWSON to Miss Phyllis Crowell, to of Ford, Ill., March 28.

## Deaths

**John Baldwin Walker** \* New York, Harvard Medical School Boston, 1888, member of the American Surgical Association and the Societe Internationale de Chirurgie and many other societies, a founder and fellow of the American College of Surgeons, formerly instructor in operative surgery and professor of clinical surgery at the Columbia University College of Physicians and Surgeons, at one time instructor in surgery assistant and associate surgeon at the New York Polyclinic Medical School and Hospital, served as a colonel in the medical reserve corps during World War I, was in command of Base Hospital 116 of the American Expeditionary Forces in France and received the Distinguished Service Medal, consulting surgeon Bellevue Hospital Manhattan State Hospital and the Hospital for the Ruptured and Crippled, trustee, Bard College and Home for Old Men and Aged Couples, author of volume IX "Hernia," in Twentieth Century Practice of Medicine, aged 82, died, April 13, in St. Luke's Hospital of arteriosclerosis.

**Thomas Reid Crowder** \* Chicago, Rush Medical College, Chicago, 1897, formerly assistant in pathology, associate in medicine and instructor in medicine and associate in genito-urinary surgery at his alma mater, past president of the American Association of Industrial Physicians and Surgeons and the American Association of Railway Chief Surgeons, formerly vice president of the Institute of Medicine of Chicago, honorary life member of the Conference of State and Provincial Health Authorities of North America, while a member of the committee of health and medical relief of the United States Railway Administration drew up a sanitation code which has since been used by nearly every state in the nation, director, department of sanitation and surgery of the Pullman Company, aged 70, died, April 15, of coronary occlusion at his home in Winnetka, Ill.

**Walter Harold McNeill Jr** \* New York, Cornell University Medical College New York 1910, associate professor of urology at the New York University College of Medicine, member of the American Urological Association, past president of the New York Central Surgeons Association, fellow of the American College of Surgeons, attending urologist and member and past president of the medical board of the Mount Vernon (N. Y.) Hospital, at various times attending urologist Bellevue Hospital and Welfare Hospital for Chronic Diseases New York and the New Rochelle (N. Y.) Hospital, consulting urologist French Hospital and New York Central Railroad, aged 56, died, March 22.

**John Paul Russell** \* Captain, U. S. Army, retired, Berkeley, Calif., George Washington University School of Medicine Washington, 1924, entered the medical corps of the U. S. Army as a first lieutenant in 1925, became a captain in 1927 and retired in 1932 for disability in line of duty, chief of the industrial hygiene service of the California State Department of Public Health since its organization in 1937, a director of the Western Association of Industrial Physicians and Surgeons, aged 41, died in March of heart disease.

**Homer William Scott**, Fort Dodge, Iowa, State University of Iowa College of Medicine, Iowa City, 1919, member of the Iowa State Medical Society and the American Urological Association, fellow of the American College of Surgeons, formerly assistant professor of surgery at his alma mater, aged 49, on the staffs of St. Joseph Mercy Hospital and the Lutheran Hospital where he died, March 23, of bronchiogenic carcinoma.

**Howard Anderson Sutton** \* Philadelphia, University of Pennsylvania Department of Medicine Philadelphia 1898, assistant demonstrator of anatomy from 1901 to 1911, assistant demonstrator of osteology 1911-1912 and instructor of osteology from 1912 to 1926 at his alma mater, for many years medical examiner in the public school system, co-author with Dr. C. K. Drinker of a book entitled Osteology and Syndesmology, aged 68, died, March 21.

**Herbert Lightstone**, London, England, University of Bishop College Faculty of Medicine Montreal, Que., Canada, 1901, served in the Spanish-American War, the Boer War and the Canadian Field Artillery and the World War, named deputy director-general of medical services in the British Ministry of Pensions in 1933 and in 1938 became acting director-general, aged 63, died, February 12, of gastric ulcer.

**Charles Sharp Bobo** \* Norman, Okla., Louisville (Ky.) Medical College 1881, an Affiliate Fellow of the American Medical Association, lecturer in forensic medicine 1907-1908,

dean and professor of forensic medicine from 1908 to 1911 at the University of Oklahoma School of Medicine, university physician, director of Ellison Infirmary from 1933 to 1937, aged 85, died, February 3, of diabetes mellitus.

**Given Campbell** \* St. Louis, St. Louis Medical College, 1889, an Affiliate Fellow of the American Medical Association, member of the American Neurological Association, formerly clinical professor of neurology at his alma mater, for many years on the visiting staff of St. Louis City Hospital, formerly on the staff of the Bethesda General Hospital, aged 74, died, April 20.

**William Taylor Webber** \* Long Beach, Calif., University of Nebraska College of Medicine, Omaha, 1922, past president of the Harbor Branch of the Los Angeles County Medical Society, served during World War I, on the staffs of the Long Beach Community, Seaside and St. Mary's Long Beach hospitals, aged 45, died, March 26, of virus pneumonia.

**Robert Malcolm Ross**, Mount Vernon, N. Y., College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois, 1906, member of the American Psychiatric Association, for many years a medical missionary in China, formerly superintendent of the Brigham Hall Hospital, Canandaigua, aged 65, died, March 24, of carcinoma.

**John William McGowan**, Oakland City, Ind., University of Louisville (Ky.) Medical Department, 1881, member of the Indiana State Medical Association, formerly member of the school board, at one time on the staff of the Methodist Episcopal Hospital, Princeton, now known as the Gibson General Hospital, aged 88, died, March 26, of myocarditis.

**Francis Henry Reilly**, New Haven, Conn., Yale University School of Medicine, New Haven, 1897, fellow of the American College of Surgeons, member of the American Urological Association, member of the selective service board 11 B, aged 65, attending surgeon Hospital of St. Raphael, where he died, March 31, of intestinal obstruction.

**Robert Burns McCay**, Sunbury, Pa., Jefferson Medical College of Philadelphia, 1900, member of the Medical Society of the State of Pennsylvania, served during World War I, chairman of the Northumberland County Draft Board number 3, on the staff of the Mary Packer Hospital, aged 65, died, March 30, of coronary embolism.

**John De Witt Byrne** \* DuQuoin, Ill., Kentucky School of Medicine Louisville, 1904, member of the American Academy of Ophthalmology and Otolaryngology, served during World War I, formerly resident in ophthalmology at the New Orleans Eye, Ear, Nose and Throat Hospital, aged 62, died, April 12.

**Francis Morgan Williams**, New York, Columbia University College of Physicians and Surgeons, New York, 1937, member of the Medical Society of the State of New York, aged 30, died, March 24, in Glasgow, Scotland, while in the employ of an American construction company.

**Jesse Frank Williams** \* Clarksburg, W. Va., Baltimore Medical College 1908, for many years member of the city board of education, formerly county health officer, on the staff of the Union Protestant Hospital, aged 60, died, March 18, of coronary thrombosis.

**W. E. Noblin**, Jackson, Miss., University of the South Medical Department, Sewanee, Tenn., 1897, member of the Mississippi State Medical Association, past president of the Central Medical Society, county and city health officer, aged 66, died, March 18.

**James Ernest Walker** \* Huntville, Ala., University of Tennessee Medical Department Nashville 1908, aged 58, died, March 20, in the Vanderbilt Hospital, Nashville, Tenn., of pneumonia as the result of a bullet wound inflicted by the father of a patient.

**Simeon Wood Johnson** \* Sheridan, Wyo., Ohio Medical University, Columbus 1898, past president and secretary of the Sheridan County Medical Society, at one time member of the state legislature, aged 71, died, March 29, of chronic myocarditis.

**Walter Lee Nicholls**, Birmingham, Ala., College of Physicians and Surgeons, Baltimore 1902, member of the Medical Association of the state of Alabama, fellow of the American College of Surgeons, aged 64, died, March 31, of coronary occlusion.

**Ralph Mozart Whitehead**, New York, College of Physicians and Surgeons of Chicago 1890, for many years ships surgeon, aged 75, was killed, March 7, when his ship was torpedoed in the Caribbean Sea.

**Edward Sherman Baker**, Kansas City, Mo., Howard University College of Medicine, Washington, D. C., 1919, formerly deputy county coroner, aged 51, died, April 14, in the Wheatley-Provident Hospital of hypertensive heart disease.

**William Henry West** ♂ Harrisburg, Pa., College of Physicians and Surgeons, medical department of Columbia College, New York, 1890, aged 76, died, March 19, in the Harrisburg Polyclinic Hospital of arteriosclerotic heart disease.

**W. S. Martin**, Carthage, Miss., Memphis (Tenn.) Hospital Medical College, 1899, member of the Mississippi State Medical Association, county health officer, aged 70, died, March 15, of chronic nephritis and valvular heart disease.

**John P. Getter** ♂ Belleville, Pa., Jefferson Medical College of Philadelphia, 1882, past president of the Mifflin County Medical Society, on the staff of the Lewiston (Pa.) Hospital, aged 84, died, March 24, of coronary occlusion.

**Felix Bailon y Hemedes**, Drexel Hill, Pa., University of Santo Tomas College of Medicine and Surgery, Manila, P. I., 1937, resident physician at the Delaware County Hospital, aged 32, died, April 9, of chronic nephritis.

**Charles Arthur Stafford** ♂ Captain, M. C., U. S. Army, native of Kennerly, Wyo., Rush Medical College, Chicago, 1937, School of Aviation Medicine, Randolph Field, Texas, 1940, was commissioned a first lieutenant in the medical corps of the U. S. Army, Nov. 8, 1939, recently stationed at Fort Douglas, Utah, aged 33, was killed in action, March 3, during the allied evacuation from Java.

**Benjamin S. Rutherford**, Bowling Green, Ky., University of Tennessee Medical Department, Nashville, 1885, formerly mayor, at one time city health officer and jail physician, aged 79, died, March 22, of chronic myocarditis.

**Archileus Crump**, Broseley, Mo., University of Nashville (Tenn.) Medical Department, 1897, member of the Missouri State Medical Association, aged 68, died recently in the Lucy Lee Hospital, Poplar Bluff, of myocarditis.

**James Francis Coyle**, New York, Cornell University Medical College, New York, 1905, member of the city health department for many years, aged 59, died, March 19, in the Lutheran Hospital of cerebral hemorrhage.

**James Wilson McLaughlin**, Austin, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1903, served during World War I, aged 64, died, March 21, of hypertensive heart disease and nephritis.

**Otis Littlefield**, Blue Hill, Maine, Medical School of Maine, Portland, 1885, three times elected to state legislature, on the staff of the Blue Hill Memorial Hospital, aged 80, died, February 4, of coronary thrombosis.

**Frederick Oliver Batteiger**, Greenville, Pa., Hahnemann Medical College and Hospital of Philadelphia, 1911, member of the Medical Society of the State of Pennsylvania, aged 55, died, February 19, of heart disease.

**Henry Clay Perkins**, Austin, Texas, Baylor University College of Medicine, Dallas, 1929, member of the State Medical Association of Texas, aged 44, died, March 14, in an automobile accident near San Marcos.

**Francis John Barnes** ♂ Cambridge, Mass., Harvard Medical School, Boston, 1888, for many years president of the board of trustees of the Walter E. Fernald State School, Waltham, aged 79, died, April 29.

**Hiram LeRoy Brockman** ♂ Greer, S. C., University of Oklahoma School of Medicine, Oklahoma City, 1920, on the staff of the Greenville (S. C.) General Hospital, aged 56, died, April 28, of multiple myeloma.

**George King Logan**, New Orleans, Medical Department of Tulane University of Louisiana, New Orleans, 1899, member of the Louisiana State Medical Society, aged 69, died, March 21, of coronary thrombosis.

**Frank C. Stewart**, Eskridge, Kan., American College of Medicine and Surgery, Chicago, 1905, member of the Kansas Medical Society, aged 63, died, March 27, in a hospital at Emporia of coronary heart disease.

**James Carlos Ghormley**, Tolovana Park, Ore., University of Oregon Medical School, Portland, 1918, member of the Oregon State Medical Society, served during World War I, aged 59, died, March 28.

**Fleeter Palmer**, Homer, La., University of Tennessee College of Medicine, Memphis, 1912, member of the Louisiana State Medical Society, parish coroner, aged 56, died, March 15, of cerebral hemorrhage.

**James W. Kinyoun**, Independence, Mo., Missouri Medical College, St. Louis, 1884, aged 83, died, March 4, in the Research Hospital, Kansas City, of arteriosclerotic heart disease and chronic nephritis.

**Charles Braxton Ingram**, Mount Gilead, N. C., Jefferson Medical College of Philadelphia, 1886, member of the Medical Society of the State of North Carolina, aged 84, died, March 5, of cerebral hemorrhage.

**Harry Blair Corl** ♂ Altoona, Pa., Jefferson Medical College of Philadelphia, 1925, aged 40, died recently in the Jefferson Hospital, Philadelphia, of subacute bacterial endocarditis and cirrhosis of the liver.

**Walter D. Patton**, Eldorado, Texas, University of Louisville (Ky.) Medical Department, 1887, member of the State Medical Association of Texas, county and city health officer, aged 83, died recently.

**Edwin Clark Babcock**, Utica, N. Y., New York Homeopathic Medical College and Hospital, New York, 1894, on the staff of the Utica Memorial Hospital, aged 69, died, April 20, of coronary thrombosis.

**Andrew Fremont Wagner** ♂ Los Angeles, University of Pennsylvania Department of Medicine, Philadelphia, 1899, for many years autopsy surgeon for Los Angeles County, aged 74, died, March 28.

**Thomas Richard Lutner** ♂ Lawton, Okla., University of Texas School of Medicine, Galveston, 1915, aged 56, died, March 7, in the Wesley Hospital, Oklahoma City, of embolism following an infection.

**Charles McCulloch**, Lexington, Va., Columbian University Medical Department, Washington, D. C., 1897, member of the Medical Society of Virginia, aged 68, died, March 13, of chronic myocarditis.

**Josiah Houston Warnick**, Abilene, Texas, Memphis (Tenn.) Hospital Medical College, 1892, member of the State Medical Association of Texas, aged 79, died, March 24, of cerebral hemorrhage.

**Robert J. Yost**, Bethlehem, Pa., Baltimore University School of Medicine, 1895, member of the Medical Society of the State of Pennsylvania, aged 71, died, February 20, of coronary occlusion.

**Seifert Clairmonte Pyle**, Charlotte, N. C., Howard University College of Medicine, Washington, D. C., 1937, on the staff of the Good Samaritan Hospital, aged 37, died in March of pneumonia.

**Ellsworth Brownell Knerr**, Portland, Ore., University of Kansas Medical College of Kansas City, Mo., 1907, member of the Missouri State Medical Association, aged 80, died, February 16, of uremia.

**William Claude Sain** ♂ Ardmore, Okla., University of Tennessee College of Medicine, Memphis, 1916, on the staff of the Hardy Sanitarium, aged 57, died, March 7, of tumor of the brain.

**John Elvin Parmer**, Mokane, Mo., University of Missouri School of Medicine, Columbia, 1894, member of the Missouri State Medical Association, aged 72, died, March 16, of chronic encephalitis.

**Herman August La Force** ♂ Joplin, Mo., Washington University School of Medicine, St. Louis, 1916, served during World War I, aged 55, died, March 31, in the Lincoln Hospital.

**Henry Milburn Faust**, Gold Dust, La., Memphis (Tenn.) Hospital Medical College, 1902, aged 68, died, March 1, in a hospital at Lecompte of gangrene of the left leg and arteriosclerosis.

### KILLED IN ACTION

CHARLES A. STAFFORD, M.D.,  
1908-1942

Morgan L. Miller, Susquehanna Pa., University of Pennsylvania Department of Medicine Philadelphia 1882, bank president, aged 81 died, March 28 in Miami, Fla., of arteriosclerosis

Thomas Van Buren Crane, Springfield Mo., Barnes Medical College, St. Louis 1903 member of the Missouri State Medical Association, aged 72, died April 10 of angina pectoris

Charles Edwin Montgomery @ Walla Walla Wash. Kentucky School of Medicine Louisville 1906, served during World War I aged 61 died, March 27 of cerebral hemorrhage

Clifford Morrison Taylor @ Westminster Md., University of Maryland School of Medicine and College of Physicians and Surgeons Baltimore 1933 aged 39, died March 25

Albert H. Miers, Mena Ark. Kansas City College of Medicine and Surgery, Kansas City Mo. 1921, aged 51 died, March 23, of coronary thrombosis and edema of the lungs

Elmer Alexander Hudson, Mercersburg Pa. Jefferson Medical College of Philadelphia 1888 served during World War I, aged 80, died, April 16, of cerebral hemorrhage

Harry Press @ New York University of Nashville (Tenn.) Medical Department, 1911 on the staff of the Gouverneur Hospital, aged 59 died February 19 of heart disease

Walter Elisha Hatch, Toledo Ohio Western Reserve University Medical Department Cleveland, 1902, aged 69, died March 28, in the Toledo Hospital of myocarditis

Harold Landow, New York, University of Pennsylvania School of Medicine Philadelphia 1937 aged 28, died March 27, in the Jewish Hospital of poison self administered

Horace Robert Peoples, Burlington Iowa, Northwestern University Medical School Chicago 1921 aged 47, died March 27, in New London of pulmonary tuberculosis

Charles Wesley Kahl, Merced Calif. College of Physicians and Surgeons of San Francisco 1899 aged 73 died, March 15, in the Mercy Hospital of arteriosclerosis

Benjamin Edward Hendrix @ Gillham, Ark., University Medical College of Kansas City Mo., 1900, for many years bank president, aged 70 died March 15 of uremia

Walter David Weil @ New York, University and Bellevue Hospital Medical College, New York 1909 aged 63, was found dead March 30, of illuminating gas poisoning

Harris Page Ilsley Limington Maine Medical School of Maine Portland 1909, member of the Maine Medical Association, aged 61, died February 16 of carcinoma

Norven Henry Gillespie @ Duluth Minn., Queen's University Faculty of Medicine Kingston Ont. Canada 1896, aged 67, died March 26, of coronary thrombosis

Theodore M. Agnew, Wichita Kan. Kansas City (Mo.) Hahnemann Medical College 1914 served during World War I, aged 52, died in April of coronary occlusion

Lucius Emilius Kimsey, Ducktown Tenn. Vanderbilt University School of Medicine Nashville 1888 aged 74, died March 13, of carcinoma of the bladder

Howard Dager, Philadelphia University of Pennsylvania Department of Medicine Philadelphia 1890, aged 77, died, March 20 of cerebral hemorrhage

John Jay Munden, Hendersonville N. C., Western Pennsylvania Medical College Pittsburgh, 1901, aged 66, died March 31 of coronary occlusion

M. Robertson Stapp @ Hesston Kan. Jefferson Medical College of Philadelphia 1889 aged 74 died March 17 in Newton of cerebral hemorrhage

Eugene A. Davis Murfreesboro Tenn. Meharry Medical College Nashville 1918 aged 50, died, March 15, of myocarditis hypertension and nephritis

Leo Edward Price @ Shelby Ohio University of Louisville (Ky.) Medical Department 1921 aged 46 died March 31 of coronary heart disease

Claude N. Workman Willow Point Texas (licensed in Texas under the Act of 1907) aged 67 died February 6 of hypertensive heart disease

John Granville Gill, Kendallville Ind. Rush Medical College Chicago 1897 aged 80 died March 26 of diabetes mellitus and myocarditis

Leonidas W. Humphreys Huntington W. Va. University of Virginia Department of Medicine Charlottesville 1901 aged 74 died April 12

Fred Lee Herbert, Andrews, N. C., Tennessee Medical College Knoxville, 1904, aged 63, died March 10 of carcinoma of the pancreas

Albert Joseph La France @ Lacombe N. H. Medical School of Maine, Portland, 1896, aged 70, died, March 12, of coronary thrombosis

George Reginald Deacon, Stratford, Ont., Canada, McGill University Faculty of Medicine, Montreal, Que., 1896, aged 67, died, March 22

Edmund Y. Hill, New York. Bellevue Hospital Medical College, New York, 1889 aged 75, died, March 30, of carcinoma of the colon

Nathan Walter Manow, Cleveland, Ohio State University College of Medicine, Columbus, 1935, aged 36, died, March 25 in Indianapolis

Charles N. McGaffey, Dallas Texas, Southwestern University Medical College, Dallas, 1908 aged 55, died, March 9, of arteriosclerosis

Joseph Benjamin Bailey, Keysville Va., Medical College of Virginia, Richmond, 1894 aged 72, died, April 6, of coronary thrombosis

William J. Orange Lee, Humboldt Tenn., Meharry Medical College Nashville, 1908, aged 63, died, March 9, of coronary thrombosis

Virgil C. Littlefield, Nixon, Texas, University of Texas School of Medicine, Galveston, 1897, aged 70, died recently in Tucson Ariz

Homer Chachere, Crowley, La., Medical Department of Tulane University of Louisiana, New Orleans, 1885, aged 83, died, March 30

Annie S. Higbie, Pasadena, Calif., New York Medical College and Hospital for Women, New York, 1903, aged 77, died March 26

Frederick Sinclair Wimberly @ Tucson Ariz., University of Texas School of Medicine, Galveston 1935, aged 32, died March 19

Samuel Arthur Looper, Hot Springs National Park, Ark., Memphis (Tenn.) Hospital Medical College, 1909, aged 67, died March 23

George Murray Shaw, Oldham, England, University of Toronto Faculty of Medicine, Toronto, Ont., Canada 1904, died, March 21

James Noah Greear, St. Paul Va., University of Virginia Department of Medicine, Charlottesville, 1883, aged 83, died March 14

Anthony Cestare, Brooklyn, Long Island College Hospital, Brooklyn 1911, aged 53 died February 26, of chronic myocarditis

George Albin Remington, Chicago, American College of Medicine and Surgery Chicago, 1905, aged 62, died, March 26

Anne McConnell Schilstra, Stembach Man. Canada, Trinity Medical College, Toronto, Ont., 1899 died recently

Lewis Franklin Soule, Salem Depot N. H. Medical School of Maine Portland, 1898, aged 72 died March 26

Marvin Cross Morris, Seattle Northwestern University Medical School, Chicago 1939 aged 31 died March 26

Merton Wheelock Brown, Ilion N. Y. Albany Medical College 1891 aged 72 died March 26 of nephritis

Isaac Newton Bourland, Equality Ill. Miami Medical College Cincinnati 1883 aged 84 died April 21

William W. Parkes, Louisville Miss. Louisville (Ky.) Medical College 1892 aged 73 died March 22

Homer Atwood Terrill, Los Angeles Rush Medical College Chicago 1884 aged 87 died February 16

Harry McMahon Barton, Walthalla S. C. Atlanta (Ga.) Medical College 1892, aged 71 died March 2

Bernard Rein, Brooklyn Cornell University Medical College New York 1905 aged 58 died March 4

George Austin Vail, Hersey Mich. Detroit College of Medicine, 1895 aged 74, died in January

Frank G. Sheffield Hastings Mich. Detroit College of Medicine 1894 aged 82 died March 30

Leland Delos Fosbury Endicott, N. Y. Albany Medical College 1904 aged 65 died March 1

Joseph Gill St. Louis American Medical College St. Louis 1907 aged 78 died March 15

## Bureau of Investigation

### HOW'S THAT AGAIN, NOW?

#### A Doctor Ohlendorf Gets Lost Among the Sublime Forces

On Aug 26, 1941 the Federal Trade Commission issued an order against William Clarence Ohlendorf, trading under the names W C Ohlendorf, Clarence Ohlendorf, C Ohlendorf and Dr Ohlendorf, 1924 Blue Island Avenue, Chicago. The respondent was ordered to cease and desist from representing that "Dr Ohlendorf's Tonic" constitutes a cure or remedy for, or that it possesses any therapeutic value in the treatment of, kidney disorders, bladder disorders, rheumatism, neuritis, diabetes or catarrh of the bladder or bowels or that the preparation will tone up the nerves or has any therapeutic value in the treatment of nervous disorders or as a diuretic.

Included in the order is the following statement: "To support his claims for the therapeutic value of his preparation, the respondent relies principally upon a scientific work published about 1795." This would seem to set some sort of record for going backward in science, until consideration is given to a release called "Nature's Sublime Forces," copyright 1942 by W C Ohlendorf, M D, Chicago. This constitutes one of the most remarkable pieces of clatter-trap that has been put in type since the invention of printing machines. Obviously based on some rather ancient material evolved prior to the advent of modern knowledge, the preface includes the following statements: "The knowledge of the Science of the Breath constitutes the object of the highest knowledge. This theory binds together widely divergent facts of medical knowledge and converges them into one point of view. The writer is indebted for his material to the Upanisads of India, Rama Prasad, and Helena P Blavatsky."

Consideration of the material indicates clearly that the writer is indebted to no one. In fact, some one, some time, somewhere, is obviously guilty of placing on record material which seems to have misled the doctor somewhat. The records of the American Medical Association indicate that Dr Ohlendorf was born in 1857 and graduated from Northwestern University Medical School, Chicago, in 1882, receiving a license to practice in Illinois the same year.

The first page of the pamphlet, which presumably was submitted by the author to the University of Chicago with the notation "Copies are 2 for a nickel. How many do you want for the students?" contains the following:

"The Tattvas are the five modifications of the Great Breath. The Great Breath is the ceaseless, eternal vibration of the Absolute. The first outcome of the evolutionary state is the Akasha Tattva (Force). After this come in order the Vayu, the Tejas, the Ap, and the Prithvi."

"The Akasha or sonorous ether throws matter which is subject to it into the form of a dotted sheet. It is said to move by fits and starts and to move in all directions. This means to say that the impulse falls back upon itself along the line of its former path on all sides of the directions of the wave. These ethers produce in gross media and in the human body vibrations similar to their own. The external form of the vibration is somewhat like the hole in the ear."

Or, as a matter of fact, like any other hole, if one totally disregards the surrounding matter.

The doctor then goes on to straighten out modern science with the following:

"From the heart ramify the Nadis, the power tube centres or carriers. Of these there are 101 principal ones. Each of these branches into 100 second order branches, of each of these again into 72,000. Thus there are 100 x 101 or 10,100 branch Nadis and 72,000 x 10,000 or 727,200,000 of the third order blood vessels. The terminology is imitated from a tree. The root is in the heart. The Susumna is that Nadi whose nervous substratum or reservoir of force is the spine."

And again

"The four petals of the heart really branch into twelve Nadis. Similarly the brain has twelve pairs of nerves. These correspond to the twelve signs of the Zodiac both in their positive and negative phases. In the Zodiacal sign the sun rises thirty one times. We have, therefore, thirty one pairs of nerves. Wherever the thirty one spinal Chakras connected with the twelve pairs of nerves in the brain pass throughout the body we have running side by side the blood vessels proceeding from the twelve Nadis of the Heart."

"In this system of Nadis moves the Prana. As the sun rises it passes into the nerves little by little. Up to noon Prana is greater in the nervous than in the venous Chakras. At noon they become equal. At sunset the Prana with its entire strength has passed into the blood vessels. Thence it gathers up into the heart and spreads towards the

nerves. At midnight the strength is equalized. In the morning the Prana is at the second spinal vertebra. The moon moves some 12 times more than the sun. Therefore, the effect of the moon is to produce 12 minor Pranic changes over a period of 24 hours. This gives a cycle of Tattvas in 2 hours or one Tattva every 24 minutes."

This quotation is followed by a paragraph entitled "Definition of Disease," which discusses further these "Pranic" changes and then states: "Disease is the result of this variation." Following this is a short paragraph on death:

"The two ordinary forms of death are the positive through the brain and the negative through the heart. If Prana becomes potential in Susumna and remains longer than for a passing moment death results. Prana is the second principle of the universe. The first principle is Manu or Mind."

Following a discussion of the pituitary body and the pineal gland, the heart is dealt with entirely by the following:

"The septenary disturbance and play of light around the pineal gland are reflected in the aura of the heart which vibrates and illumines the seven brains of the heart just as does the aura round the pineal gland. And the heart has 7 cavities, 3 superior and 4 inferior corresponding to the 7 principles in nature and man."

Under the heading "Definition of Insanity," the following appears:

"The definitions of insanity as given in the text books of medicine and neurology are very poor, and, as the present medical teachings overemphasize the gross body and woefully neglect the inner man and his six principles, the student and practitioner do not gain a comprehensive view of neurology as they do of the other branches of medicine. Insanity is a severance of the Atma and Buddhi principle from the Manas, i.e. breaking off of the 6th and 7th principles from the lower 5th principle, the mind. Keeping this definition in mind one is immediately in a better position to understand insanity."

One of the closing paragraphs of the twenty-two page pamphlet is entitled "The Science of Breath." Under this heading the following misinformation is expounded:

"The lamp of the five Tattvas receives its oil from the moon (allegorically). Protect it from the solar force. Life will thereby become long and stationary. If, by mastering the flow of breath, the sun is kept in check, life is prolonged."

"He whose breath flows by the Pingala two whole days and nights has two years to live."

"He whose breath flows from one nostril for three nights has one year to live."

"When the skin is cool and the inside hot, death comes within one month."

"He who suddenly begins to feel heavy bodies light and vice versa and he who being dark in color begins in disease to look gold colored must die."

"He whose hands, chest and feet become at once very dry after bathing has not ten nights to live."

"If a man sees the figure of the messenger of death he is sure to die. (The messenger of death has red clothes, matted hair, diseased teeth, oil besmeared body, a weeping and red hot face, a body besmeared with ashes, flying flames of fire having long rods and standing towards the empty Nadi.)"

The opus closes with the sentence "So much for this short and condensed article on Nature's Sublime Forces. There is no knowledge beyond the secret knowledge of the Five Tattvas."

All of which makes it fairly obvious that it would not be unusual for this individual to promote a remedy in 1941 which was based on scientific work published about 1795. After all, that is fairly recent in comparison with the age represented by the limitations of knowledge exemplified by the quotation.

### SOME MISCELLANEOUS MEDICAL FRAUDS

#### A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of THE JOURNAL. Following are brief abstracts of some fraud orders not dealt with previously.

**Arthur B Jacobson**—This person was reported to be a teacher of industrial arts in the high school at Upsala, Minn. On the 4th of May 1941 he conducted a mail order business in which he promoted a "Better Eyes System" by representations to the effect that by means of Jacobson's eye cure and correct presbyopia, myopia, hyperopia and aigmatism would enable all persons wearing properly fitted glasses for refractory errors to see equally well at close or long range as of their visual acuity, that it would strengthen the eyes of all and enable all persons suffering from eyestrain to see easily, clearly and without the slightest eye discomfort, that it would quench the vision, would cause no harm and that all users must be similar to those reported in the alleged testimonials that Jacobson published. In February 1941 the Post Office ordered Jacobson's

on March 24 why a fraud order should not be issued against him. Although his attorneys filed his reply which was a general denial of the charges neither they nor Jacobson appeared at the hearing. The hearing revealed that Jacobson had claimed that for eight years he had conducted numerous experiments and represented that the system which he promoted through the mails was the result of his personal experiments. The evidence presented at the hearing showed that he employed no physicians or other person qualified to diagnose and treat eye diseases and disorders. It further showed that he sent to inquirers something called an eye tester which he described as a new invention (patent pending) which assists you to quickly and easily set your eyes right in your own home. His system consisted of various charts and a set of instructions concerning exercises purporting to have the following effects: strengthening the muscles of both eyes; developing the seeing strength of the weaker eye; stimulating the sight centers; gaining eye coordination; increasing the range of accommodation for distances and correcting the unevenness in curvature of the eyeball. On purchasing the system however the customer found that special eye disorders such as cataracts, anisokonia, glaucoma, trachoma, etc. require the attention of specialists who have studied these conditions. The hearing also revealed that within the previous six months Jacobson had changed the instructions that go with his system so that it consisted of a seven day course of exercises for eyes. Out of Balance with additional exercises to be used during the second week of the treatment for cases of astigmatism, near sightedness and far sightedness. Previously the instructions had recommended exercises for those who were near sighted or far sighted to be performed on the first four days of an eight day course. The government's expert witness, a physician who specializes in the field of eye diseases, testified at considerable length on the subject and summarized his evidence with the statement that Jacobson's Better Eyesight System would have no effect on any part of the eye except the extraocular muscles. Accordingly the Post Office debarred Jacobson's scheme from the mails by issuing a fraud order against him on June 7, 1941. In the meantime another government agency, the Federal Trade Commission, had been investigating the same scheme and after a series of hearings the Commission reported on Jan. 12, 1942 that it had ordered Jacobson to cease and desist from certain statements in the advertising that the Commission regarded as misrepresentations. Among these were that the treatment is new and revolutionary, will improve the eyesight, eliminate headaches, nervousness and tired feeling, correct near sightedness, astigmatism and strabismus without resorting to glasses, drugs or surgery, and that 90 per cent of the physical defects of the eye can be remedied by the use of Jacobson's devices and courses of instruction.

**Manuel Solera Viquez**—This person at San Jose, Costa Rica, in connection with one Bruce Watts at Leslie, Ark., sold through the mails a nostrum called Senatica by means of what the Post Office charged were fraudulent pretenses to the effect that except in cases in which syphilis is present the product would quickly cure arthritis and kindred conditions regardless of the duration, severity or chronicity of the ailment and would prove of great value in the treatment of kidney disorders, fevers, high blood pressure, hemorrhoids, insomnia and some other things and that it was harmless. According to the evidence the Costa Rica man was the principal promoter of the scheme and had authorized Watts to act as his agent in the United States. When the Post Office notified Solera Viquez to show cause on Dec. 20, 1939 why he should not be debarred from the mails for conducting a fraudulent scheme he denied the charges by letter and later an attorney from Washington, D. C., representing him appeared in his behalf and obtained a form of affidavit under the terms of which Solera Viquez would be bound to discontinue his nostrum business. Not long thereafter the attorney filed with the Post Office a statement wherein Solera Viquez expressed a desire to continue selling his product through the mails. His attorney was informed that such a proposal was not acceptable. Thereafter the original affidavit bearing Solera Viquez's signature was filed with the Post Office and sworn to before the United States consul at San Jose, Costa Rica. On Dec. 18, 1939, an answer to the charges also was received from Bruce Watts who filed an affidavit a few days later in which he promised to abandon the business. Nevertheless evidence subsequently developed that Solera Viquez had resumed the operation of this fraud. According to a government chemist the Senatica preparations were composed of herbs or leaves of a species of cassia and one of the wild guavas and the user was to make a tea from them and to follow a diet which provided for plenty of milk and fruits, especially oranges and blackberries, but banned all meats. Since expert medical evidence showed that such a mixture would not produce the effects claimed for Senatica a fraud order was issued on Jan. 10, 1942, debarring Manuel Solera Viquez from further use of the mails.

**Myraene Company National Distributors Inc.** and Mr. and Mrs. W. A. Summers—The concerns in question were operated from Chester, Ark., with W. A. Summers as manager and Mrs. W. A. Summers as secretary. They used the mails to promote Myraene as a genuine Indian remedy for rheumatism, chills and fever, stomach, liver, kidney and bladder disorders, all diseases of the skin and some other conditions. For the tobacco habit they sold Nico-Ban. After due investigation of the scheme the Post Office ordered these respondents to show cause on May 27, 1941 why a fraud order should not be issued against them for using the mails to promote a scheme by means of false and fraudulent pretenses, representations and promises. W. A. Summers filed an answer in which he denied the charges but he put in no appearance at the hearing. On that occasion a government chemist and a microanalyst testified that Myraene was revealed in their examinations as a finely ground yellow brown powder composed of yellow dock and licorice roots. The user could take it in either dry or tea form. An expert medical witness testified that such a mixture would have merely a mildly irritant and laxative effect and could not act as a miracle tonic, renew

bodily vigor, restore lost sex functions in men and women or overcome the long list of ailments in the advertising. Nico-Ban, according to the government chemists, was found to consist of yellowish brown uncoated tablets containing the roots of gentian, licorice and yellow dock as well as some starchy material. The directions were to take a tablet as often as desired, hold it in the mouth until dissolved and swallow the saliva. An expert medical witness for the government testified that this nostrum certainly was not a reliable remedy for all forms of the tobacco habit as had been represented that it would not furnish a substitute for any of the systemic effects furnished by tobacco or in any way decrease the desire for tobacco. Together Myraene and Nico-Ban constituted according to the Post Office a scheme for fleecing the public and a fraud order was issued on Oct. 23, 1941, against the Myraene Company, National Distributors Inc., W. A. Summers, Manager, and Mrs. W. A. Summers, Secretary, with their officers and agents.

**Tarex Company**—This Los Angeles business was started in 1935 by a Jacob Baum who claimed to have incorporated it in California. Through the mails he sold Tarex No. 1 and Tarex No. 2 under representations that the first named would overcome all cases of eczema in its various forms regardless of duration and that the second would "clear up any case of psoriasis of whatever long standing, banish all unsightly marks and restore the skin to a normal healthy appearance. The Post Office regarded these representations as unwarranted and ordered the Tarex Company and an E. T. Baum (presumably the secretary, Mrs. Tyler Cromwell, formerly Ethel T. Baum) to show cause on April 25, 1941 why a fraud order should not be issued against them. Jacob Baum, president, then requested and obtained a continuance to May 12, 1941 but did not appear at the hearing, send a representative or file an answer denying the charges. There did appear a qualified medical expert and a chemist who testified for the government. Baum had not disclosed to the Post Office inspector in the case the formula of either preparation but had stated that Tarex No. 1 contained tar and that both products were based on a formula developed by a physician alleged to be the head of a Los Angeles hospital but neither the physician nor the institution could be identified in the American Medical Association's records. The government chemist testified at the hearing that his analysis had shown Tarex No. 1 to be a greenish black salve consisting chiefly of petrolatum 45 per cent, starch 45 per cent, coal tar 5 per cent and about the same proportion of zinc oxide. Tarex No. 2 he reported was an ointment chiefly consisting of wool fat with 7.8 per cent of salicylic acid and 5.75 per cent of ammoniated mercury. The lengthy testimony offered by the government's expert medical witness showed in substance that these mixtures would not cure the conditions cited in the advertising and on July 16, 1941 the Tarex Company and its officers and agents were debarred from the mails by a Post Office fraud order. Previously another government agency had taken action against the Tarex Company. On June 8, 1938, the Federal Trade Commission announced that it had ordered this concern to cease representing in any way that its products are effective remedies and cures for eczema and psoriasis in any form or are any more than palliatives for such conditions.

**Vita Laboratories, Hessel Laboratories and Hessel's Oil**—Under these various trade styles one Eugene Hessel conducted a mail order business from Philadelphia and promoted two patent medicines known as Hessel's Oil and Hessel's Oil Salve. According to the representations the first named when used as directed would prove an effective, reliable, successful and harmless remedy for and would effect astounding results in the treatment of almost all illnesses including paralytic stroke, food poisoning, rheumatism, sinus disorder, stomach and bowel ailments, heart trouble, hay fever, asthma and some other things and that the salve when used as directed would work like magic and produce healing results in rectal disorders including hemorrhoids. The Post Office considered these representations to be false and fraudulent and ordered Hessel to show cause on April 11, 1941 why a fraud order should not be issued against him and his trade styles. The hearing finally took place on May 6 but neither Hessel nor any one representing him put in an appearance although the defendant had issued a general denial through his attorney. Hence the only testimony offered was that given by government witnesses who included the Post Office inspector who had investigated the case, a chemist and two physicians. The chemist testified that both Hessel's Oil and Hessel's Oil Salve were composed essentially of ordinary oil of peppermint. The medical testimony presented was to the effect that these preparations when applied externally and in accordance with the directions might in some instances by means of their peppermint content act as a mild counterirritant and produce a slight reddening of the skin together with a slight tingling sensation. It also was shown that when taken internally the oil would produce some local irritant effects on the mucous membrane of the stomach and cause gaseous eructations without however causing any systemic effects. The medical testimony further showed that Hessel's Oil whether used externally or internally would be incapable of healing any of the disorders named and certainly no astounding results would be effected. On Sept. 29, 1941 a fraud order was issued to debar Eugene Hessel from further operating through the mails under the names of Vita Laboratories, Hessel Laboratories and Hessel's Oil. The testimony in this case brought out the fact that in the years 1933, 1937 and 1938, proceedings were instituted against Eugene Hessel under the Federal Food and Drug Act on the ground that his peppermint oil preparation which during those years was sold under different names (Hessel's Oil de Vita, Snuff and Hessel's Oil de Vita Salve) bore false and fraudulent therapeutic claims on its label and that in one of these proceedings Hessel had entered a plea of guilty in a district federal court to being sentenced to pay a fine and in addition to have been named as perpetrator for a year. Nevertheless as the Post Office memorandum stated he was still making similar claims at the time that the Post Office began its investigation.

## Correspondence

### IMMOBILIZATION IN INFANTILE PARALYSIS

*To the Editor*—To my knowledge, the practice of immobilization in the treatment of poliomyelitis in the acute or initial stage was first questioned years ago by the late Henry O Feiss, an orthopedic surgeon of Cleveland. As early as 1912 he (Feiss, H O. *Experimental Studies of Paralysis in Dogs After Mechanical Lesions in Their Spinal Cords, with a Note on "Fusion" Attempted in the Cauda Equina of the Sciatic Nerves, J Compar Neurol* 22 99 [April] 1912) became interested in the problem of nerve regeneration. He operated on dogs, producing mechanical lesions and a clinical picture roughly resembling that of infantile paralysis. He allowed his animals to move about without splinting the muscles. He also reported on the question of nerve fusion, and incidentally a part of one of his techniques was nerve crushing.

More than twenty-five years ago, Feiss was talking about the early treatment of infantile paralysis. He felt that immobilization procedures, as recommended by the Harvard Infantile Paralysis Commission (Lovett, R W. *The Treatment of Infantile Paralysis*, ed 2, Philadelphia, P Blakiston's Son & Co, 1917), which consisted chiefly in maintaining from the very start the greatest rest and fixation that might be obtained by the use of recumbency, rest and splints, were not physiologic in their application. In such treatment he remarked that a patient might be placed on his back and strapped to a frame for a period of six weeks or more, a type of fixation applicable to every case without regard to individual symptoms. He remarked frequently that he did not believe in this accepted method of treatment because disuse of muscles in the early stage of infantile paralysis was directly opposed to physiologic indications. He taught that most muscles were in reasonably good condition at the beginning of the disease.

Subsequently he publicly demonstrated the results of this method of treatment (The Academy of Medicine of Cleveland, Oct 21, 1921) and wrote about them in *THE JOURNAL* (Feiss, H O. *The Treatment of Early Infantile Paralysis Based on the Physiologic Indications*, Jan 14, 1922, p 85) and in the *Ohio State Medical Journal* (Early Activation of Muscles in Infantile Paralysis, *Ohio State M J* 19 177 [March] 1923).

This editorial comment prefaced Feiss's article in the *Ohio State Medical Journal*. "While it may not seem important to some practitioners to begin the activation of muscles as soon as possible in infantile paralysis, on account of the erstwhile fear of doing damage instead of good, it has been Dr Feiss's experience that early activation is not only the method of choice, but that it also saves weeks and months of convalescence as well as the long, trying period of parental suspense. There is nothing so sustaining to the morale of the little patient and those concerned in their child's recovery as the realization that something serious is being done to effect a cure."

Feiss (*The Treatment of Early Infantile Paralysis Based on the Physiologic Indications*) wrote of the motor functions in striated muscles: "(1) that willed by effort, (2) subconscious and (3) reflex." In early infantile paralysis he thought that it was necessary to make trial of all three types of functions and referred to voluntary will and effort. This to him consisted in directing the patient's attention to movements in the affected muscles. He frequently demonstrated to me that there was a subconscious subjective appreciation of movement on the part of the patient long before the movement was objectively appreciated by the examiner, and he instituted procedures in young children by which the subconscious and reflex pathways were

utilized. As stated by him, such technic consisted "in establishing a so-called 'receptor field,' a term borrowed by him from Sherrington (*The Integrative Action of the Nervous System*, New York, Charles Scribner's Sons, 1906). In the light of recent events, Feiss's vision was almost prophetic when he stated that "once a path is opened through any given receptor field, movement may be gained by several other methods of stimulation."

JOHN A TOOMEY, M D,  
Division of Contagious Diseases, City Hospital,  
Cleveland

### PSITTACOSIS

*To the Editor*—In his recent article entitled "Psittacosis" (*THE JOURNAL*, April 4, p 1214), Dr Henry Alicandri reports that the pigeons epidemiologically connected with the human case of psittacosis which he describes were sent to the Hooper Foundation for examination. It may be of general interest to report on the observations made on a sample of pigeons secured by the New York City Department of Health from the yard where the patient had paid a casual visit on Sept 28, 1941, ten days before he became ill. The flock consisted of 12 pigeons showing no signs of illness. The patient did not handle the birds. Five of the pigeons (*Columba livia*) were bled and the serums subjected to the complement fixation test in the presence of a parakeet psittacosis antigen. The serums of 2 reacted in dilutions of 1:128 to 1:256, and of 2 others in dilutions of from 1:8 to 1:16. A typical ornithotic, or pigeon psittacotic, virus was isolated from the spleen and kidneys of 1 pigeon which reacted in a dilution of 1:16. Although the evidence strongly incriminates the pigeon loft as the probable source of infection, it would have been of great interest had the patient's sputum been examined for the virus. It is extremely important that in the future the sputum of the patient and the viruses isolated from the kidneys or spleen of the pigeons be subjected to a comparative study in order to prove the etiologic relationship suspected on inductive epidemiologic evidence. The ubiquitous ornithotic infections in pigeons (up to 50 per cent in some lofts, plazas and parks) expose many people to fleeting accidental contact with the virus. Probably mild atypical human infections escape detection, while those with frank pulmonary lesions without a serologic test remain etiologically obscure, since they are clinically diagnosed as influenza, atypical pneumonia or the like.

San Francisco

### NOSE DROP CONTAMINATION

*To the Editor*—Here are further suggestions to be added to those of Gompertz and Michael in their article on nose drop contamination (*THE JOURNAL*, April 11, p 1287).

In prescribing nasal medication I ask the pharmacist to supply an empty quarter ounce (7.5 cm) dropper bottle and direct the patient to fill this bottle half way. When this amount is put up the bottle and dropper are to be rinsed in hot water and the bottle refilled. Where there is more than one patient to use the prescribed medication, each one has his own quarter ounce dropper bottle.

Moreover, in using such medication, it might be more easily used when the patient is instructed to draw up in the dropper 1/2 inch of medication, which is about 3 drops, and squirt the amount into each nostril. I have often wondered how to interpret and apply the usual drop numbered direction.

GEORGE ABELOFF, M D, Brooklyn

## Medical Examinations and Licensure

### COMING EXAMINATIONS AND MEETINGS

#### BOARDS OF MEDICAL EXAMINERS

##### BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL May 23 page 367

#### NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS *Parts I and II* Various centers June 22-24 *Part III* Various centers June or July Exec Sec Mr Everett S Elwood 225 S 15th St Philadelphia

#### EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY *Oral Part II* Atlantic City June 6-7 Sec Dr Paul M Wood 745 Fifth Ave New York

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY *Oral Groups A and B* Cleveland Jan 14-15 1943 Final date for filing application is Dec. 7 *Written* Various centers Nov 16 Final date for filing application is Oct 5 Sec Dr C Guy Lane 416 Marlboro St Boston

AMERICAN BOARD OF INTERNAL MEDICINE *Written* Oct 19 Final date for filing application is Sept 1 Sec Dr William S Middleton 1501 University Ave Madison Wis

AMERICAN BOARD OF OPHTHALMOLOGY *Oral* Baltimore June 6 and Philadelphia June 8 Sec Dr John Green 6830 Waterman Ave St Louis

AMERICAN BOARD OF ORTHOPAEDIC SURGERY *Oral and Written* Chicago Jan 9-10 Final date for filing application is Nov 1 Sec Dr Guy A Caldwell 3505 Prvian St New Orleans

AMERICAN BOARD OF PATHOLOGY *Oral and Written* Richmond Va Nov 9-10 Final date for filing application is Sept 1 Sec Dr F W Hartman Henry Ford Hospital Detroit

AMERICAN BOARD OF PEDIATRICS *Written* Locally Sept 18 *Oral* Chicago Nov 23 Final date for filing application is July 1 Sec Dr C A Aldrich 707 Fullerton Ave Chicago

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY New York December Final date for filing application is Oct 1 Sec Dr Walter Freeman 1028 Connecticut Ave N W Washington D C

AMERICAN BOARD OF UROLOGY If a sufficient number of applications are received an examination will be held in the east at the same time or shortly after one of the national meetings Sec Dr Gilbert J Thomas 1409 Willow St Minneapolis

### Ohio January Report

The Ohio State Medical Board reports 13 physicians licensed to practice medicine by endorsement on January 6 The following schools were represented

| School   | LICENSED BY ENDORSEMENT | Year Grad | Endorsement of |

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

Dental Practice Acts Advertisements Containing a Guaranty and False and Misleading Statements—The Business and Professions Code of California, Section 1680, defines what constitutes "unprofessional conduct" on the part of a dentist for which a license may be suspended or revoked The following conduct is included within the definition

The advertising of professional superiority or the performance of professional services in a superior manner

The making use of any advertising statements of a character tending to deceive or mislead the public

The advertising to guarantee any dental service

The petitioner in this case caused an advertisement to be published which in the opinion of the Board of Dental Examiners of California contravened these provisions and his license to practice dentistry was suspended for six months He then filed a petition in the superior court for a writ of mandate to compel the board to reinstate his license and from an adverse judgment appealed to the Supreme Court of California

The court disagreed with the petitioner's contention that administrative proceedings to revoke a professional license are quasi criminal in nature and that the rules concerning the burden and quantum of proof applicable to criminal trials should have been applied in the hearings before the board Where the court said, the legislature has created a professional board and has conferred on it power to administer the provisions of a general regulatory plan governing the members of a profession the overwhelming weight of authority rejects any analogy which would require such a board to conduct its proceedings for the revocation of a license in accordance with theories developed in the field of criminal law

In answer to the petitioner's contention that the evidence introduced before the board and the superior court was insufficient to support the order of suspension the court pointed out that the only evidence in the case consisted of the advertisement itself and the testimony of the petitioner The advertisement stated among other things This new material will absolutely not change in color Does not stain from smoking, alcohol or alkaloids will not shrink or warp" and "These new dental plates are so ably designed that Dr Webster challenges you to detect any false appearance Each tooth is set so that it appears to be growing there Dr Webster's Immediate Restoration Dentures or plates are faithful reproductions of your own natural gums and teeth, in their true color, size and form These plates are made to defy detection most intimate friends need not know that you are wearing artificial teeth The petitioner contended that these statements did not constitute a binding guaranty and were too general to come within the statutory prohibition It was clear to the court however that if this view were accepted and the rules of contract thus imported into the statute the purpose of the law would be defeated The law was designed to prohibit advertising which induces the reader to believe that a dentist proposes to guarantee a particular result The law does not merely forbid a contractual guaranty of a particular dental service the court said but instead prohibits any advertising to guarantee any dental service that is advertising which represents that a guaranty may be forthcoming Under this interpretation the court thought that the statute had been violated

The court also held that the advertisement tended to deceive or mislead the public It stated Dr Webster's Immediate Restoration Plate Material Weighs Less than 1 Oz This beautiful plate material made from a secret formula is a development of dental science which many plate wearers have been thankful for and also Have Your Dental Plate Made The Webster Way of Immediate Restoration The ordinary reader said the court was given the unmistakable impression by this language that the petitioner used a secret type of plate material not generally available and that his plates etc made

according to a unique method called "The Webster Way" of Immediate Restoration." The petitioner testified, however, that he had no secret material not available to the entire profession and that his methods were no different from those in general use. The petitioner argued that the statute prohibited only statements which were actually untrue and that the untruth of his statements had not been proven. In the field of ordinary commercial advertising, said the Supreme Court, regulatory agencies which are charged with the duty of combating false or misleading advertising are not required to prove that the particular deceptive statements are actually false. In view of such a conclusion concerning ordinary commercial advertising, the court held that it would be unthinkable to accord a more stringent construction to a statute regulating one of the learned professions so intimately connected with public health and safety.

Finally the petitioner contended that the board's order was void because no proper findings to support it were made. The court, held, however, that where the findings of the board, either by a restatement of the charge made or by reference to the language of the accusation, sufficiently points out the specific ground on which it has determined that a cause for suspension or revocation exists it cannot be said that an order so based is void.

The judgment of the superior court for the Board of Dental Examiners was therefore affirmed—*Webster v Board of Dental Examiners of California*, 110 P (2d) 992 (Calif, 1941).

**Rabies Paralysis and Death Following Administration of Vaccine**—The deceased, having been exposed to rabies, submitted to the administration of a vaccine manufactured by the defendant. Thereafter he suffered "an ascending myelitis of the spinal cord, atelectasis lower lobes of both lungs, quadriplegia," as a result of which he died. His widow, both individually and as administratrix of her husband's estate, sued the defendant for damages for the wrongful death, claiming that the defendant was negligent in failing adequately to warn her husband and his physician of the danger involved in the use of the vaccine. At the close of the plaintiff's evidence, the trial court sustained the defendant's motion for a directed verdict and entered judgment thereon. The plaintiff then appealed to the appellate court of Indiana.

The evidence showed that accompanying the package of vaccine was a pamphlet containing, among other things, the following specific warnings of the risk involved in its use:

#### REMOTE ILL EFFECTS OF TREATMENT

Occasionally, in addition to the local reactions observed during treatment, there have been disturbances ascribed to the treatment, such as "treatment paralysis" coming on during the treatment or immediately afterward, and in a very few cases a fatal paralysis has occurred. Remlinger in the study of 107,712 cases, found forty cases of paralysis, 2 resulting fatally.

It is not easy to explain the paralysis, and a number of causes have been suggested. It is rarely met with in children, it is relatively more common in syphilitics, alcoholics, persons under severe nervous strain, and brain workers. It is to be remembered, too, that a person who has been bitten by a rabid dog is likely to have nervous and hysterical symptoms.

It is well for the physicians to have these facts in mind although the dangers are very remote and do not affect the value or necessity of treatment.

Prior to administering the vaccine, the physician showed the husband the pamphlet, went through it with him page by page and told him that, while there was a possibility that paralysis would follow treatment, the possibility was a remote one.

There was no charge that the vaccine was improperly prepared or manufactured. The gist of the plaintiff's complaint was that the defendant had negligently marketed, sold and recommended its antirabic vaccine treatment with misleading representations in the pamphlet and without sufficiently warning prospective users of its danger. The appellate court held that the husband was fully informed and was in no way misled as to the possible effects of the vaccine. In the opinion of the court, the evidence conclusively showed that the physician knew all the dangers and risks of the use of the vaccine and that he told the husband about them. With this information

and with the information contained in the pamphlet, the husband decided to take the treatment. The hospital records disclosed that the husband was "a regular daily drinker of whisky and that upon occasions he would take many drinks in a day." The pamphlet, pointed out that paralysis "is relatively more common in syphilitics, alcoholics, persons under severe nervous strain, and brain workers." Any reasonable adult lay person reading the pamphlet would be reasonably informed of all the dangers incident in the use of the vaccine, the court said. The duty of the defendant was adequately to warn of the dangers incurred in the use of its vaccine and, in the opinion of the court, the pamphlet met all the legal requirements. The judgment for the defendant was affirmed—*Carmen v Eli Lilly & Co*, 32 N E (2d) 729 (Ind, 1941).

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1952 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Asphyxia Neonatorum.**—Lund observed that among 1982 consecutive deliveries nitrous oxide ethylene and cyclopropane when used as an analgesic did not materially influence the incidence of neonatal asphyxia. However, when cyclopropane and agents other than nitrous oxide were used in anesthetic concentrations there was an increase in the incidence of fetal asphyxia. Prematurity, the complications of pregnancy and labor, the method of delivery and the misuse of analgesic agents were of greater significance in neonatal asphyxia than were the various inhalation agents when properly administered.

**Radium in Uterine Bleeding.**—Randall and his associates analyzed the follow-up records of 196 women whose atypical uterine bleeding (menorrhagia and/or metrorrhagia) caused by benign conditions was treated five or more years ago with radium or roentgen rays. For women in the first half of reproductive life treatment should aim to regulate and preserve the menstrual function. A fair percentage of successful results has been obtained with doses of from 150 to 300 millicurie hours for women less than 30. Varying initial doses of radium given to 79 women 40 or less years of age without demonstrable myomas produced satisfactory results in 47. An additional 10 patients given subsequent radium treatment had good results. Hysterectomy was required by 12 patients before the bleeding was controlled and 8 had severe menopausal symptoms. Four pregnancies occurred among the 64 married women. Of 35 patients 40 or less years of age who had myomas 15 obtained satisfactory results following the initial dose of radium. 1 patient had a subsequent application of radium. 17 had a subsequent hysterectomy and 4 complained of severe menopausal symptoms. Of the 30 married women only 1 became pregnant after treatment. Twenty-five of the 27 patients aged more than 40 who

did not have myomas obtained satisfactory results after 1,000 or more millicurie hours of radium treatment. Four of these patients had severe menopausal symptoms and 1 died of a pulmonary embolus on the fourteenth day after dilation, curettage and insertion of radium. Of 20 similar patients who had myomas the results were satisfactory for 18 and 1 had severe menopausal symptoms. The results of abdominal and vaginal application of radium were satisfactory in 10 of 14 patients in both age groups. Two patients experienced severe menopausal symptoms and one pregnancy occurred among the 12 married women. Of 21 women with functional uterine bleeding treated with 700 to 1,760 roentgens 19 experienced satisfactory results. The bleeding of the 13 aged more than 40 was controlled with the initial dose of roentgen rays. Among the 8 patients aged 40 or less, 1 required further roentgen therapy and 1 patient a hysterectomy. There were no deaths following roentgen therapy.

**Uterine Packs with Sulfanilamide.**—Anderson and his co-workers used uterine packs impregnated with sulfanilamide to control postpartum hemorrhage in 37 women. The results were compared with those obtained with twenty-seven plain packs and six iodoform packs. The average length of time that packs remained in the uterus was fifty-four and one-half hours for the sulfanilamide, forty-three hours for the plain and forty-two and one-half hours for the iodoform. The uncorrected morbidity (temperature of 100.4 F or more) was 72 per cent for the plain packs, 38 per cent for the sulfanilamide and 20 per cent for the iodoform pack. In the sulfanilamide group, 1 patient had a severe paronychia with a temperature of 102 F during the first five postpartum days, another patient had acute sinusitis with a temperature of 104 F following delivery and a third was thought to have an acute appendicitis but instead a hematoma was found in the region of the infundibulopelvic ligament, this in the operator's judgment was not produced by the uterine pack. All rises of temperature of patients in the plain pack group were considered to be due directly to the packs. Two of these patients had a rather severe acute endometritis, and bacteriologic study of both showed nonhemolytic streptococci aerobically and Staphylococcus aureus and albus on anaerobic culture. Both were treated with sulfathiazole and recovered. If the sulfanilamide pack, the authors point out had no therapeutic virtue other than removing vaginal odor, its use would be justified. Almost without exception there was no odor while the pack was in place or after it was removed. The purpose of the sulfanilamide pack is prophylactic because of the bacteriostatic action of the drug at the site of contact.

**Pregnancy in Syphilitic Mother.**—Benenson discusses the results of antisyphilitic treatment for 935 pregnancies that occurred in 722 syphilitic women. A previous survey disclosed that among pregnant patients who had weakly positive Wassermann reactions and who were not treated 35 per cent had syphilitic complications. This led to a careful search for other evidence of syphilis and when a suggestive history was obtained, therapy was instituted even though an occasional patient was treated unnecessarily. Treatment prior to delivery consisted of a minimum of five to a maximum of forty weekly intravenous injections of 0.6 Gm of nearsphenamine and 0.13 Gm of bismuth salicylate or 0.2 Gm of bismarsen intramuscularly. There were no rest intervals during the antepartum period. If at any time syphilis was suspected or diagnosed in the infant he was referred to another agency for therapy. The mother was offered treatment for one year after delivery. About 17 per cent of the patients returned pregnant again within one to two years. All patients before discharge were urged to resume treatment whenever they became pregnant. The data reveal that only 39 per cent of all untreated mothers transmit the infection to the fetus as compared to 67 per cent in the entire group. The results among 350 patients receiving more than ten treatments were especially noteworthy: there were only fifteen failures. Study shows conclusively that patients receiving adequate therapy, particularly those also treated before pregnancy, can be completely prevented from transmitting syphilis. Third generation syphilis was extremely rare. The dangers of arsenic therapy to the mother (one death among the 722 patients due to arsenical exfoliative dermatitis) must always be considered and treatment should be stopped at the slightest indication that a reaction may be imminent.

**Amphetamine in Treatment of Alcoholism**—Bloomberg administered amphetamine sulfate as an adjunct in the treatment of 56 patients with chronic alcoholism. This therapy effectively combated the depression and general malaise of the acute "hangover" and continued to combat these symptoms throughout the weeks of readjustment following the total withdrawal of alcohol. The amphetamine sulfate was as effective as alcohol in overcoming the depression and jitters of the hangover. It made it possible for the patient to stop drinking with no consequent great discomfort. The drug makes hospitalization for readjustment unnecessary for most patients. This is of enormous psychologic value, as a week of voluntary abstinence is better than six months of enforced and involuntary teetotalism. The fact that amphetamine gives an immediately perceptible effect and helps the process in the first few days makes rapport between patient and physician much easier to attain. Something tangible and specific has been done for the patient and his immediate unpleasant symptoms, and he is much more willing to try to cure himself by "talking." Alcoholic addicts are accustomed to solve their difficulties by ingesting something, usually alcohol, and it appears reasonable to them that something they ingest should help them. Amphetamine is substituted for alcohol in the habit pattern, yet the effect is good rather than bad and the internal logic of the situation for them is satisfied. Furthermore, after the first few weeks

amphetamine smooths out mood swings and gives the patient the kind of "lift" on his bad days that he had always hoped but never did get from alcohol. Frequently patients being treated with the drug say that they "have no more craving for liquor." What they probably mean is that with amphetamine they are able to face their life situations without alcohol. The drug was extremely useful as an aid to whatever other therapy was being administered. Some patients have responded to amphetamine without any other therapy. In the whole series, the degree of modified drinking habits, the number of total abstainers and the number of generally good results would appear to be greater than that usually expected with other psychiatric methods. These results warrant further trial.

**Lateral Aberrant Thyroid**—Frantz and his associates urge surgical intervention for the lateral aberrant thyroid which at first appears as a relatively benign lesion. A tumor was present in 27 of their 30 patients with a lateral aberrant thyroid and in 23 of the 27 the lesion was malignant. There were 8 deaths among the 23 patients. They believe that by the surgical approach at least some of the late unexpected deaths may be avoided. To determine the true nature of these tumors a follow-up study is essential. The distinction between a tumor of a lateral aberrant thyroid and metastasis to cervical lymph nodes from carcinoma of the thyroid is difficult and at times impossible. The authors make a diagnosis of metastasis only when groups of tumor cells lie scattered in a structure having the architecture of a lymph node, i e marginal sinus, sinusoids and lymph follicles. Biopsy of one or more nodules is advised and, if the study shows the lesion to be benign, all the nodules should be removed, because many such tumors with a long history of stationary masses subsequently were proved to be carcinoma. If the biopsy shows malignant disease with or without involvement of the lymph nodes a radical neck dissection is advisable, on both sides if the disease is bilateral. If the thyroid is involved, partial or complete thyroidectomy is indicated. Evidence on the effect of roentgenotherapy is meager, but at least 2 patients appeared to have the disease arrested. Others had recurrences during treatment. However, it is the only therapeutic measure for a tumor which is considered inoperable. All these tumors should be considered potentially malignant, treated radically and followed indefinitely.

**Black Widow Spider Bite**—Kirby-Smith believes that bites by *Latrodectus mactans*, the black widow spider, are more frequently than is generally supposed. He has collected 15 cases from the records of the Vanderbilt Hospital and encountered 9 cases during five years of private practice. Fourteen of the 24 patients were reported before 1933. Fourteen of the 24 patients actually saw the spider, and the history and subsequent course of symptoms of the other 10 leave no doubt that they were bitten by the black widow. Eleven of the bites were on the penis, four on the buttocks, one on the scrotum or thigh, four on the arms and hands one on the chest.

the knee and the site of one was not mentioned. Sixteen of the victims were bitten while in a privy. Twenty-two of the patients were male. Symptoms ensued from five minutes to two and a half hours after the bite. The bites were inflicted from April through October. There was 1 death and in 1 case a mistaken diagnosis led to echiotomy. Death following a bite by a black widow spider is uncommon despite the report by Bogen who collected approximately 600 cases with 40 deaths. The record of these deaths were not obtained from published articles but from death certificates, newspaper reports and personal communication. Among 248 cases collected from literature there were no recorded fatalities. Judging from the cases reviewed it appears to Kirby Smith that arachnidism usually results in complete recovery without sequelae in three days or less.

**Neuropathic Arthropathy.**—Kernwein and Lyon report a case of a neuropathic joint. There are three theories of pathogenesis advanced for neuropathic joints: the traumatic, the trophic and the mechanical theory. In many persons with elastic tibiae dorsalis including ataxia, hypotonia and loss of sensibility deep in the joint neuropathic joints never develop. In others with bilateral sensory changes only unilateral neuropathies develop. In the latter a history of trauma to the afflicted limb can usually be elicited. The events of the injury is overlooked because pain is absent. Inadequate treatment results in the rapid development of a neuropathic joint. That the loss of articular sensation alone does not cause a neuropathic joint to develop in man is therefore apparent. That destruction of articular sensation by cutting the posterior roots does produce a neuropathic joint in dogs, cats or rabbits has been repeatedly confirmed. The authors' case supports the mechanical theory. Severance of the sciatic nerve resulted in the development of a combined motor and sensory lesion. Definite atrophic changes appeared in the muscles of the leg and the ankle relaxed because of loss of motor nerve supply. The sensory loss was characterized by a decided ataxia and anesthesia below the knee. The trauma associated with the act of walking on such a limb was often excessive because the protective sense of pain was absent. This was sufficient to cause the joint to disintegrate. Roentgenograms of the ankle revealed changes typical of those ascribed to neuropathic joints. The opposing articular surfaces with some sclerosis but no atrophy showed particular destruction. Disseminated throughout the enlarged joint were numerous fragments of bone. An unusual feature was the extra articular migration of particles of bone which caused shadows in the roentgenograms. As the periosteum was stripped by the distended capsule radiating spicules or new bone were present on the lateral surface of the fibula and mesial surface of the tibia.

**Gastroduodenal Ulcer.**—Dragstedt states that the chemical and mechanical traumas produced by the normal content of the stomach are not sufficient to cause ulcers in the normal gastric and duodenal mucosa and to prevent them from heal-

ing or to delay the healing of an extensive artificial lesion. This resistance to the digestive action of the normal content of the stomach is not only limited to the gastric and the duodenal mucosa but is displayed by the spleen, the kidney and the pancreas. Pure gastric juice, on the other hand, can destroy and digest all living tissue including the gastric wall. In this effect the gross and the microscopic appearance of the typical progressive ulcer and the associated gastritis in man are exactly reproduced in the experimental animal. Under normal conditions the gastric wall is not digested away because it is not exposed to pure gastric juice. Food which is the stimulus for the formation of gastric juice is also the chief factor that protects gastric tissue against its corrosive activity. Pancreatic juice, gastric and intestinal mucus, duodenal juice and bile (probably in the order named) constitute an additional protective mechanism for the duodenal the gastric and the jejunal mucosa. When an excessive amount of normal gastric juice is continuously secreted by the experimental animal this defensive neutralizing mechanism is overcome and ulcer ensues. It is probable that in man a similar excessive secretion occurs and ulcer results. Hypersecretion is most likely neurogenic and abnormal in that it operates when food the usual stimulus for gastric secretion, is absent.

**Surgical Treatment of Duodenal Ulcer.**—Although duodenal ulcer responds well to conservative measures complications which require surgical intervention develop in about 20 per cent of patients with this functional disorder. The patient with a complication Allen says is usually the victim of ulceration in an area that gives no warning or activation until massive hemorrhage perforation duodenal or pyloric stenosis or intractability takes place. For acute perforation simple closure of the perforation combined with proper after-care is all that is indicated. The patient with a massive hemorrhage from duodenal ulcer must be hospitalized immediately. With conservative treatment in a patient less than 45 the hemorrhage will cease spontaneously and after complete recovery an elective subtotal gastrectomy is advised. Patients more than 45 years of age are likely to bleed to death in spite of the best conservative care. Their condition should be evaluated on admission and radical surgical intervention undertaken within seventy-hours after the onset of bleeding. If the delay has exceeded three days conservative treatment should be continued as the aged patient will rarely withstand radical operation after a week or more of repeated hemorrhage and starvation. Posterior gastroenterostomy, pyloroplasty and gastroduodenostomy are indicated only for cicatricial obstruction in the aged patient. Surgical cure of the duodenal ulcer can be brought about only by subtotal gastrectomy meaning the elimination of all the acid activating cells in the antrum and a large proportion of the acid cells in the fundus of the stomach. The operative mortality of the procedure is compatible with the results obtained.

**Incidence of Tuberculous Infection.**—To determine the validity of the tuberculin test as an indicator of the incidence of tuberculous infection Carnes examined post mortem a representative sample of 536 patients aged 6 weeks to 89 years whose death was not due to tuberculosis. The data from a plotted frequency curve show a rapid increase in acquiring the infection in the first few years of life. The steepest part of the curve lies between the ages of 10 and 15 and indicates an increase in the infected portion of the population examined or about 25 per cent in this brief span of life. The curve also indicates that by the age of 20 approximately 70 per cent of the

individuals are infected. After this age the incidence rises more and more slowly and approximates 100 per cent after the age of 60. The incidence of infection among the entire adult population of the community (calculated on the urban population of Maryland, U S Bureau of the Census, 1940) is estimated at approximately 90 per cent. If the curve does represent the true incidence of infection in Baltimore today, its most important implication is that a considerable body of young adults exists who have had no previous immunization against tuberculosis. The prevailing doctrine of the pathogenesis of adult tuberculosis would require that the childhood type of disease develop in these individuals when exposed. However, the proportion of noninfected young adults was sufficiently large to allow some doubt of the doctrine that previous infection is necessary for the development of the adult type of disease. The analysis did not include the type or location of the lesion, but the mesenteric lesion was encountered infrequently, four among the one hundred and fifty-three mesenteries roentgenographed. The four lesions had the characteristics of a primary intestinal complex, but in two there was also evidence of a primary type of pulmonary infection. Such lesions were not found in 84 individuals aged less than 20 years. The results suggest a moderate fall in the incidence of infection in adults since the study of Opie in St. Louis in 1916, however, the statistical comparison of these data does not yield a conclusive answer. Analysis of the numerous anatomic European investigations carried out in this century shows considerable local differences in incidence. The more recent European surveys do not reveal any great change in the past generation in spite of a decided decline in mortality. These considerations make it essential that similar anatomic surveys be conducted in numerous localities in the United States before any conclusion regarding the present prevalence of the disease in this country is reached. The effect of a lower mortality and morbidity on the extent of its distribution in the population can be evaluated only after such studies have been repeated at intervals in the same localities. A comparison of the available tuberculin and anatomic surveys suggests that the decided decrease in the rate of exposure of the population in recent times may have resulted in a greater decrease in the number of infected persons who maintain their hypersensitivity than in the proportion of infected individuals. This is supported by the increasing frequency with which calcified lesions are found in individuals who do not react to tuberculin.

**Surgical Treatment of Duodenal Ulcer**—Buchbinder points out that the goal of operative treatment of chronic duodenal ulcer is anacidity and a rapid gastric emptying time. Postoperative failure of surgical cure is usually associated with the failure to obtain both of these conditions. Used indiscriminately or as routine, gastrojejunostomy will fail in a large percentage of cases. Wide gastric resection, while not routinely possible, by accomplishing anacidity and a rapid emptying time in the largest percentage of recurring and marginal ulcer is the most desirable operative procedure. In certain instances its use is mandatory, and increasing experience with a definitely lowered mortality rate has made it applicable in most cases.

**Bronchospirography**—Pinner and his associates show that bronchospirographic studies within the field of pulmonary function tests are of practical value. Bronchospirography permits the determination of the total pulmonary function of each lung. In all lungs that are severely damaged functionally, pleural involvement appears to play an important part. Lungs with strictly parenchymal lesions even when far advanced, frequently have only a slightly decreased pulmonary function. Reexpanded pneumothorax lungs may or may not show extensive functional limitation. Thoracoplasty lungs, if not complicated by diaphragmatic paralysis, participate to a considerable degree in respiration. In lungs damaged by disease or treatment respiration is usually much more limited than ventilation. Therefore their function should not be judged only by their vital capacity. Clinical and roentgen studies do not provide a reliable indicator of the functional pulmonary capacity.

**Extrapariosteal Pneumonolysis**—Bailey attempted to overcome the more serious complications of extrapleural pneumothorax and thoracoplasty by an extrapariosteal pneumonolysis. He felt that the phenomena of paradoxical breathing, mediastinal flutter atelectasis and bronchiogenic spread following thoracoplasty were due mainly to the less rigid wall of the chest and to the resultant impairment of the cough function. These symptoms are absent after extrapleural pneumothorax, even though the area collapsed is much greater. Several collapse methods were freely drawn on in devising the operation. The usual thoracoplasty incision is made, and the estimated number of ribs are denuded of periosteum from the transverse processes to nearly the costal cartilage. A 2½ inch piece of the second rib is resected, and the periosteum on the under surface of the first rib is removed. An extensive Semb apicolysis is performed, freeing the apex down to the hilus and continuing down to the lowest denuded rib. The intercostal muscles, nerves and vessels are cut posteriorly so that the lung is mobilized out of the gutter. The anterior attachments of the

intercostals are left intact. This leaves an anterior portion of adherent tissue so that Davidson's modification of the Monaldi method may be employed safely in cases of check valve cavity. The wound is closed in the usual thoracoplasty manner. The space is maintained by aspirations and refills. After three to six months bone regeneration is practically complete on the pulmonary surface, rendering the collapse permanent. Any time after two months, the pneumonolysis may be safely and readily converted into a thoracoplasty by removing the denuded ribs. It is questionable whether this second operation can or should be avoided. Nineteen patients have undergone the operation with no bronchiogenic spread or serious paradoxical breathing. Up to ten ribs have been stripped at one time in patients aged from 15 to 57 years. In several patients the vital capacities were between 1,300 and 1,500 cc, and 3 had acute exudative fibril disease. Of 15 patients with unilateral involvement the operation in 11 was performed more than two months ago, 1 of the 11 died six weeks later as a result of manic depressive psychosis, wound rupture, secondary infection and inanition, and the cavities of 10 are closed and their sputum is converted. The operation of 1 of the 4 with bilateral involvement is very recent; the sputum of 1 is negative (having had contralateral clearing); the sputum of 1 is positive from the other side and the patient is now having pneumothorax therapy, and 1 died of contralateral progression ten months later. Further observation must determine the eventual value of the procedure.

**Preventing Injury to Diaphragm in Nephrectomy**

It occurred to Lazarus that the convalescence of nephrectomy could be reduced to a minimum and injury to the diaphragm to which the renal capsule might be adherent avoided by completely dividing the capsule surrounding the upper pole of the kidney, leaving it attached to the under surface of the diaphragm and removing the remainder of the capsule along with the kidney to which it is adherent.

**Radium in Treatment of Carcinoma of Bladder**

Between January 1930 and January 1941, 279 patients who had carcinoma of the bladder were treated by Herger and Sauer with radon implants, 50 were treated with radon implants alone, while 179 also received interstitial irradiation radium pack or electrocoagulation with loop resection either alone or in combination before or after interstitial irradiation. Two hundred and twenty-nine could be traced as to development, clinical course and radium reaction. Telangiectasis or ureteral stricture was not frequent but ulceration was observed in 195 (80.7 per cent) of the patients. In 53 the ulceration was

complicated by incrustation or stone or both. In 103 the ulceration healed and in 92 it persisted either until death or to the follow-up study. The tendency toward the formation of ulceration was least in low grade malignant papillary carcinomas and greatest in highly malignant papillary tumors and solid infiltrating cancers. There was a tendency for ulceration to form in tumors originating in the vesical sphincter or center and border of the trigone, while the prognosis of lesions of the anterior and posterior wall of the bladder was better as to the development and the healing of radium ulceration. Data from 179 patients with single tumors as to the factors that influence the clinical course and the duration of radium ulcerations were collected. The results show that the tendency of radium ulceration to persist is in direct proportion to the size of the area implanted and to the amount of radium delivered. The percentage of persistent ulceration was 62.5 per cent for lesions of from 4 to 5 cm and 71.4 per cent for lesions larger than 5 cm in diameter. If more than 3,000 millicurie hours was delivered, the ulcer persisted in two thirds of the cases. The average duration of radium ulceration when healing took place was ten and six-tenths months. Ulceration of the anterior and posterior wall of the bladder healed faster than that located in the fixed parts of the bladder. Incrustation or stone also prolonged the duration of the radium ulcers.

**Acute Appendicitis**—Cutler and Hoerr state that the mortality rate for acute appendicitis, at least in the Peter Bent Brigham Hospital, remains the same as it was twenty-five years ago despite the advancement in technical surgery. The only way to decrease the rate is to prevent the avoidable deaths of patients who reach the doctor too sick or who take medicine without consulting a physician. A part of the

blame rests with the "corner drug store," but above all the public must be spoken to as a mass, educated in medical matters and even perhaps prevented by laws from taking medical advice from those not competent to give it. Such a move would save more lives than all the improvements in technical surgery which may come in the next twenty-five years. The total mortality for the 2,192 cases of acute unruptured appendicitis, acute perforated appendicitis or appendical abscess encountered at the hospital from 1913 to 1940 was 4.4 per cent, and for the three types of appendicitis it was 1.2, 1.71 and 7.3 per cent, respectively. Today the proportion of cases with perforation or abscess is still greater than 20 per cent, indicating the need of a public educational campaign. An analysis by five year periods shows no significant improvement in the mortality trends for any of the three groups despite the availability of gastro-intestinal siphonage, parenteral fluid therapy and the sulfonamide drugs. A distinct advantage is shown for the McBurney incision, particularly in the acute unruptured appendix that has been drained. The low mortality in undrained cases further encourages restriction of drainage. Study of 14 patients who died during the last three years discloses that 6 died of extra-abdominal complications, 4 of peritonitis despite treatment with the sulfonamide drugs, and that no death could be attributed to the fact that drainage was not instituted. All but 3 of the 14 had symptoms for forty-eight hours or longer before coming to the hospital, and 8 had taken a cathartic (several on the advice of a physician). The disease can be attacked best through earlier diagnosis and treatment rather than through the skilful management of late cases.

**Testosterone Propionate for Mammary Pain**—Nathanson and his collaborators treated mammary swelling and pain or chronic cystic mastitis whether or not there was secretion from the nipple, with testosterone propionate. Experimental data in animals suggest that prolonged administration of the substance reduces the secretory activity and probably the number of cells of the breast epithelium and that its action on the vascular bed of the breast may relieve the venous congestion and edema so often seen in these patients. Increased secretion, increased vascularity and edema are usually responsible for the swelling and pain, symptoms and signs which only after the fluid is absorbed or diminished disappear. Nine patients with adenofibrosis and 21 with nonpuerperal mammary disease were treated by injecting intramuscularly 1 cc of testosterone propionate in sesame oil. The injections were given every other day. For a few patients testosterone made up in a hydrous wool fat base was utilized as an ointment. Treatment was begun about two weeks prior to the next expected menstruation. If the symptoms were of long duration the cycle, it was started a few days before the symptoms were expected and continued up to the period. Treatment was given for longer than three months unless there was a

period of one to several months before its resumption. Eighteen of the 21 patients with mammary secretion were subjectively improved or completely relieved. Thirteen patients had inhibition of secretion during treatment. Eleven of the 30 patients had been previously treated, without success, with estrogen. The most obviously predominant and noticeable clinical effect was a reduction or inhibition of premenstrual swelling. If secretion was not completely inhibited it was reduced. Symptoms and physical signs usually recurred after treatment was discontinued. Few patients were relieved for more than six months without resuming treatment. Prolonged and continuous treatment is to be discouraged as planned periods of treatment followed by adequate intervals of rest accomplish as much.

**Prothrombin Levels**—White and his colleagues determined the blood prothrombin level of 100 patients with hepatic and biliary disease encountered as routine diagnostic problems. About seven hundred tests were made. The prothrombin percentage and its response to vitamin K was compared with the excretion of hippuric acid and urobilinogen in the urine and fractional bromsulphalein elimination from the blood. The correlation between the prothrombin level and the hepatic function tests was decidedly poor. The prothrombin test did not reveal the milder grades of hepatic damage. It was abnormal in only 53 per cent of the patients and may be normal when hepatic damage is extreme and easily revealed by the other tests. The prothrombin level with the exception of discovering the bleeding tendency was of less definite prognostic value than the hepatic function tests used. An abnormal test is significant, if a low prothrombin level rises but little fails to rise or falls after vitamin K treatment the prognosis is progressively unfavorable. In acute hepatitis a falling prothrombin level in the presence of adequate vitamin K usually means irreversible widespread hepatic damage. In the differential diagnosis of hepatic disease the prothrombin level is of only suggestive and limited value. The sole diagnostic differential is that the prothrombin percentage is much more likely to rise rapidly to normal after vitamin K treatment in obstructive jaundice and healing acute hepatitis than in chronic hepatitis (cirrhosis). Some patients with acute hepatitis and a low initial prothrombin level have had a rapid response to active dextrose and fluid intake comparable to that in similar patients treated with vitamin K. Bleeding in hepatic cirrhosis was about as frequently due to ruptured varices as to a low prothrombin level.

**Serodiagnosis of Trichinosis**—A complement fixation test for the serodiagnosis of human trichinosis was developed by Witebsky and his co-workers. They tried two different methods. The first was performed by mixing a 1:500 and a 1:2,000 dilution of trichina antigen with a 1:5 or 1:10 dilution of inac-

tivated serum from the patient. This is put in the ice box for two to three hours and then it is placed in the incubator for one hour. For the second method a 1:2,000 dilution of boiled trichina antigen is mixed with serial dilutions of the patient's serum such as 1:5, 1:10 and 1:20. The latter method is preferred. Out of one thousand human control serums examined in this way only one definite positive reaction in both complement fixation and precipitation tests was obtained. The serum was from a healthy blood donor with no history of trichinosis. The test can be carried out as a quantitative procedure and the increase and decrease of antibody titer can be observed over a period of time.

**Cutaneous Acidity**—Bernstein and Herrmann measure the acidity of the skin by using the Stansien universal indicator with a  $pH$  range between 1 and 11. One drop of the indicator solution is dropped by pipet on the skin. The size of the drop should be kept constant and the solution should be stirred with equalized glass rods for five seconds each time. Immediately after the performance of the reaction the test drop is drawn up into a capillary. The resulting color of fluid in the capillary is compared with the given standard color shades. The test should be performed on many different areas. Not only the places affected by a dermatosis but also apparently normal parts should be tested. The figures are of value only when compared with the  $pH$  of the normal skin. The authors observed that the acidity on the normal skin is increased during hot days that the skin is alkalinized by washing with soap and that the reduced tendency to soap dermatitis in summer can be explained by the increase in (free) perspiration. When eczema is present the  $pH$  of the affected region is moderately higher than of the normal skin of the same person. This difference remains for some time after an apparent cure. Hyperhidrosis shows  $pH$  values that are either normal or on the acid side. These persist on hyperhidrotic inflammatory areas. Dyshidrosis is characterized by a lack of acidity. This lack can be either (1) primary, idiopathic and generalized (most definite in intertriginous areas), (2) secondary caused by external factors, as uncleanness and dust, (3) localized on areas with reduced evaporation due to anatomic peculiarities or (4) circumscribed, due to external mechanical factors. The figures for intertriginous mycosis are similar to those for eczema. The presence of fungi may be indicated by finding an 'inner' area of a lower  $pH$  within a surrounding zone of dyshidrosis with a higher  $pH$ . The normal acidity is reduced when degenerative changes, myxedema and senile atrophy prevent the skin from imbibition with sweat.

**Osteopoiikilosis**—McLean reports the occurrence of disseminated osteosclerosis in a boy of 20. Roentgenograms of the shoulder, acromial process, scapula, clavicle, pelvis, head of the humerus and the long bones of the legs, hands, feet and forearms showed the characteristic mottled appearance. The patient's mother was not affected. However, the patient's father aged 70 has a few scattered spots in the hands, feet and pelvis. It is possible that at his age the spots have become absorbed and, as the causative factor is no longer operative, no new ones have formed. The author thinks that the condition in the father represents a terminal stage of osteopoiikilosis and that if the condition in the son could be studied up to the same relative age a gradual disappearance of the spots would occur. The patient has two sisters living in California who have not been examined.

**The Unrelieved Cholecystectomized Patient**—Senger ascribed the frequent occurrence of postcholecystectomy pain to mistakes made by the patient, the internist and the surgeon. The patient often fears an operation and therefore delays it. When his existence becomes intolerable he begs the surgeon to perform a miracle. The internist by training is more conservative than the surgeon. He sees all the poor results, rarely the good ones. Therefore he is prone to procrastinate with diets and sedatives. The surgeon must bear in mind that (1) if the gallbladder is found to be normal he should let honesty overrule pride and leave it alone, (2) exploration of the common duct is indicated if the pancreas is enlarged and hard from pancreatitis, if stones can be felt, if the wall of the common duct is thickened, if the gallbladder is filled with small stones and if there is a history of jaundice and chills, (3) he must be certain that no fragment of stone is left in the cystic duct, (4) he must peritonealize the bed of the gallbladder and (5) the incidence of postoperative hernia can be reduced by proper drainage and suturing of the wound.

**Subdural Hematoma in Infants**—Downman and Kahn state that subdural hematoma in infancy and early childhood is seldom thought of in differential diagnosis and therefore it is frequently not recognized. Subdural hematoma should be considered in a child with slight to moderate enlargement of the head, in whom hydrocephalus is suspected, particularly when the facial expression is more intelligent than that of the average hydrocephalic child. Subdural hematoma should also be suspected in infants with feeding problems, convulsions, palsies, opisthotonos, meningeal signs and drowsiness, with or without a history of injury. The condition is fairly frequent in illegitimate,

bottle fed, poorly nourished infants, probably because they are more exposed to injury. The increased capillary fragility in scorbutic patients may also play a part. Diagnostic bilateral fontanel puncture of the subdural space should not be used indiscriminately, but the space should be investigated whenever the intracranial pressure appears increased. Nine cases are reported, 1 of them is probably the first reported example of an infected subdural hematoma in an infant. The other 8 were chronic subdural hematomas. In 6 of the infants the lesions were bilateral. The condition of the child with the infected lesion was exceedingly poor and he was treated by bilateral trephining and drainage, as it was felt that less bone would be sacrificed by this method. The other 8 infants were submitted to osteoplastic craniotomy, with only one death. The favorable results, the authors feel, are due to three improvements. 1 The entire procedure was carried out under local anesthesia, with drop ether anesthesia carried only to the stage of sedation. 2 A smaller incision was employed. It facilitated closure and thereby reduced the total operating time and lessened surgical shock. 3 Blood transfusion was begun when the patient was put on the operating table, preventing shock. These infants rarely live, once shock supervenes. Of the surviving infant 2 are definitely retarded, 2 are apparently normal, 3 have been operated on too recently to permit definite conclusions to be drawn and 1 could not be followed.

**Tumors of Adrenal Cortex**—Cahill and his colleagues discuss the tumors of the adrenal cortex encountered at the Squier Clinic. The conclusion is drawn that, among adrenal syndromes, tumor of the adrenal cortex occurs infrequently. When it occurs there may be no symptoms showing it. There is any change in the hormone balance. In other words, symptoms due to hormone influences are present. These symptoms vary according to the hormones secreted, to their amount, to the age and sex of the individual. The anatomic change in the adrenal gland is ascertained by air insufflation in the perirenal facial spaces. All the tumors so diagnosed by the authors were confirmed by operation. A simple and reliable method for estimating all the androgens excreted in the

especially as the symptoms of androgenic excess are more frequent than any others. A large amount of estrogen is excreted in the urine of patients with the adrenogenital syndrome with virilism. In young girls with virilism due to a tumor much estrogen was excreted before the tumor was removed but after removal it continued unchanged although the virilism receded. The estimation of the estrogen is particularly necessary in those rare instances of male patients with femininity due to tumor of the adrenal cortex. The identification of other ketosteroids associated with tumors of the adrenal cortex is as yet in an unknown state. Three different routes of approach have been used for removing the adrenals: (1) the extraperitoneal through the lumbar region, (2) the trans-thoracic and (3) the transperitoneal. Shock brought about by an acute deficiency of adrenal cortex extract often occurs immediately or shortly after an adrenal tumor is removed. Walters and Kepler have stated that the most important factor in surgical therapy of tumors of the adrenal cortex is the anticipation, prevention and control of postoperative deficiency of adrenal cortex extract. In this the authors concur but believe that the mechanism occurs only in the Cushing syndrome because with the androgenic type of tumor there is no functional atrophy of the opposing adrenal. The method of prevention is that used in the crisis of Addison's disease: the preoperative and postoperative administration of desoxycorticosterone. Adequate amounts of sodium chloride and sodium citrate should also be given orally or parenterally. Since in the Cushing syndrome an erythrocytemia exists an immediate postoperative transfusion is necessary. A preoperative diet low in potassium might be of value. Walters and Kepler have been able to tide the patient over the crisis by replacement therapy. The remaining adrenal tissue will regain its capacity to excrete sufficient hormones to meet the needs of the body. Patients with androgenic changes do not need replacement therapy if an opposing adrenal can be demonstrated by air insufflation. The tumor was usually a soft, encapsulated adenoma that did not show any invasive characteristics microscopically, or a carcinoma the microscopic sections of which varied from tumor to tumor. The more the syndrome approached the Cushing type the more profuse were the vacuoles. Fuchsinophil staining of the cytoplasm was present in all the tumors, in some diffusely, in others in granules. It apparently was more pronounced in cases with the hormone syndrome.

**Clostridium Welchii Infections**—Sewell and his associates feel that a number of cases of *Clostridium welchii* infection do not belong among the "gas gangrene" cases. For this group the term "clostridium infection" seems inadequate but "clostridium cellulitis" is reasonably descriptive. Here conservative surgery and either a sulfonamide or roentgen irradiation gives the best therapeutic results. Amputation is warranted only when the vascular bed is decidedly compromised. Sulfanilamide or roentgen irradiation when employed alone has some beneficial effect on the course of the clinical and experimental infection. Sulfadiazine was used in 3 cases with success. The prophylactic use of the sulfonamide drugs is invariably superior to their use after infection has set in. Experimentally the combined use of sulfadiazine and roentgen irradiation has given poorer results than has the use of either separately. *Clostridium welchii* antiserum is of some efficacy only when additional therapy is used to combat the local lesion. At present conservative surgery and sulfadiazine are recommended.

**Problems of Surgery in Total War**—Gordon-Taylor discusses certain clinical phenomena of wounds which appear to be novel in this conflict of total war which makes no sex or age distinctions. Six hundred operations for abdominal injury incurred in naval and air warfare during indiscriminate civilian air bombardment and the flotsam and jetsam of the 'Dunkirk miracle' are reviewed. The environment of total war has been responsible for rupture of the spleen incurred by a fall on a stone floor from an air raid shelter bunk, by the fall of a soldier on his tin hat or of a sailor on his gas mask. Perforated peptic ulcers have been dealt with successfully in hospitals during air raids and even in the woods adjacent to

the Dunkirk beach. Despite the gravity of the abdominal wounds and the frequent association of multiple injuries, approximately 50 per cent of the patients for whom operation was possible survived. Few patients survived lengthy intestinal resections. Sulfonamide therapy locally and orally has proved of inestimable value. The transfusion of blood or blood derivatives has made operation possible in many cases that otherwise would have been fatal. For many through and through abdominothoracic wounds of the right side produced by a small fragment no immediate active surgical treatment is required if no gross damage is present in the thoracic or abdominal wall, if the track of the missile is not in the peritoneal cavity and if abdominal hemorrhage or injury to a hollow viscus is absent. For right sided abdominothoracic wounds with an inaccessible small fragment expectant treatment is the correct procedure. Accessible fragments should be removed. When an open, blowing thoracic wound is associated with a "stove-in chest" the chest must be treated first. If the track of entry and exit of a missile in a left sided abdominothoracic injury is obscured but injury to the left subphrenic area of the abdomen is suggested or if a fragment of metal in this region is demonstrated roentgenologically, the thorax should be dealt with first and access to the upper part of the abdomen obtained through the diaphragm. When intraperitoneal damage is widespread and the hollow viscera are involved, exploratory laparotomy is indicated. Often a slight thoracic injury with an extraperitoneal course of a small fragment may be left alone. For an abdominothoracic injury that occurred through the abdominal aspect time should not be taken to complete a difficult suture of the diaphragm if the patient is critically ill unless the aperture is so large that immediate herniation of the abdominal contents is certain. There is no successful operation for sub-parietal nonpenetrating abdominothoracic injuries involving the diaphragm. Present experience shows that abdominothoracic injuries due to fragments of a high explosive or of bullets are far less grave than those due to crushing force or to blast. Diaphragmatic hernia, especially that produced by injury, is approached by the thoracic route in Britain. The general surgeon also avails himself of a thoracic approach when removing the lower end of the esophagus or the cardiac end of the stomach.

**Treatment of Burns**—Penberthy and Weller epitomize the present management of the severe burn. The factors influencing their prognosis are general care, combating disturbances in general tissue metabolism, adequate treatment of shock, the correction of hemoconcentration, combating dehydration, raising the blood pressure to normal, restoring and maintaining capillary tone and preventing toxicity. An extensive burn is comparable to a large open wound and deserves rigid aseptic surgical care, thorough cleansing and debridement. Failure to adhere to the basic surgical principles in preparing the burned area, especially in war zones has led to adverse criticism of the tannic acid method. Uniformity of opinion on the development of toxemia in severe and extensive burns is lacking. On the basis of bacterial invasion of the local lesion and the presence of concurrent infections the authors instituted chemotherapy in 1939 with close clinical observation for complications or unfavorable reactions. There have been no deaths or serious reactions in 75 severely burned patients treated to date by the addition of chemotherapy. The local use of certain sulfonamide derivatives may aid in preventing local infection or in retarding bacterial invasion, and as the drug is absorbed it may have beneficial effects on septicemia. Local therapy is not without danger, however, as the rate of absorption is not controlled, high blood levels may occur and acetyl-sulfathiazole crystals may form in the renal pelvis. Further experimental study of local therapy is indicated. The use of a freshly prepared 5 per cent aqueous solution of tannic acid has stood the test of time. The use of a 10 per cent solution of silver nitrate and a 5 per cent solution of tannic acid applied either as a spray or as a jelly is of distinct value. Methyl-rosaniline in a 1 per cent aqueous solution is preferred for infected burns or for burns of more than forty-eight hours duration. Burns involving the perineum the hand and the foot those encircling an extremity or those in the region of a

joint should be treated with methylrosaniline, as the more pliable coagulum obviates splitting of the protective coating over articulations and permits increased freedom. The dye may be used after tannic acid when the coagulum has separated and infection about the edges of the coagulum is present. The combination of methylrosaniline and silver nitrate produces a firm coagulum, drying is more rapid and staining is lessened. Also the antiseptic properties of methylrosaniline appear to be increased by the silver nitrate. Tannic acid jelly may be used effectively for certain burns of the hand and face, but in other instances it may be best to apply saline compresses or a water soluble jelly to which has been added 2 to 5 per cent of sodium chloride followed by pressure bandages. After the coagulum has separated, early grafting of extensive granulating surfaces has saved the lives of many patients. It should be done as soon as the local lesion is sufficiently prepared to assure success. This also minimizes scarring and deformity.

**Spondylitis Adolescents**—Blair suggests that spondylitis adolescents is not an infectious process but is caused primarily by absorption of cartilage from the joints involved, that the beneficial results of roentgen therapy are apparently due to the liberation of sulfur within the body in a usable form and that the associated iritis is caused by the same metabolic disturbance and may possibly react to the same treatment. In spondylitis adolescents chondroitin sulfuric acid is absorbed from the cartilage, ligaments and bone in and around the sacroiliac joints and spine, and this absorption probably occurs because of a deficiency of sulfur, mucosin or chondroitin sulfuric acid elsewhere in the body. In 1925 Cavadias stated that it is not illogical to assume that a certain hereditary or constitutional predisposition exists for sulfur demineralization. He believed that sulfur demineralization is a special metabolic disturbance in rheumatoid arthritis and that the tissues lose the power to retain sulfur.

**Study of Sarcoma of Stomach**—Lemon and Broders believe that gastric leiomyosarcoma, hemangioendothelioma and fibrosarcoma comprise a distinct group of nonepithelial neoplasms differing from lymphosarcoma. The clinical and pathologic features of gastric sarcoma are correlated with the three foregoing types on the basis of 14 microscopically proved cases of gastric sarcoma, exclusive of lymphosarcoma, in which operation was performed at the Mayo Clinic between 1908 and 1938 inclusive. The cause of gastric sarcoma is not known. Evidence points to its origin in normal cells, congenital isolated cell rests, traumatized or inflamed tissues, benign tumors and

gastric ulcers. All sarcomas of the stomach may be classified into four types: lymphosarcoma, leiomyosarcoma, hemangioendothelioma or angiosarcoma and fibrosarcoma. The last three most often involve the curvatures of the stomach, more rarely the pylorus or cardia. They originate in the submucous or muscular layers of the wall of the stomach, are usually well circumscribed, are often pedunculated and tend to assume an exogastric or endogastric form, rarely they are infiltrating. They may be composed of large or small round or spindle cells, depending on the proliferative activity of the growth and the amount of cellular differentiation. Microscopically the cells group themselves in interlacing bundles and whorls. The malignant grade of leiomyosarcoma, hemangioendothelioma and fibrosarcoma is average, metastasis occurs in about a third of the cases, the most common site being the regional perigastric lymph nodes or the liver. The clinical manifestations of gastric sarcoma generally are indistinguishable from those of any other malignant or sometimes benign gastric tumor. The sarcomas are confused most often with gastric carcinoma, peptic ulcer and benign bleeding gastric leiomyoma. There are no definite pathognomonic signs, symptoms or laboratory criteria on which to base a diagnosis before operation, although roentgen study usually establishes the malignant nature of the lesion. The matter of prime importance is to recognize the malignant nature of the neoplasm. The onset of the disease, although usually insidious, may be sudden, and the symptoms may vary from mild dyspepsia to the severe manifestations of gastric carcinoma. The course of the tumors is relatively slow. The average duration of symptoms before treatment was three and a half years. The chief signs and symptoms, in order of frequency, are pain, nausea and vomiting, abdominal tumor, melena, weakness and pallor, digestive disturbances, hematemesis and loss of weight. Frequently the history is suggestive of peptic ulcer. In the differential diagnosis carcinoma, benign tumors, cysts and ulcers of the stomach and the abdominal viscera must be considered. The prognosis, while guarded, is better than that of lymphosarcoma or carcinoma. The more mature the cells and the slower the growth, the better is the prognosis. There were no operative or immediate postoperative deaths among the 14 patients. The treatment for leiomyosarcoma, hemangioendothelioma or fibrosarcoma is surgical intervention. Lymphosarcoma responds to irradiation, but it is of little value in other types of gastric sarcoma.

**Pneumonia as Complication of Biliary Colic**—Levine and Schneider report 11 cases of biliary colic complicated by pneumonia. Severe epigastric pain or pain in the right upper quadrant prompted the patient to seek help, the pneumonia came as an unpleasant surprise and proved to be most annoying and at times hazardous. The exact mechanism that causes pulmonary inflammation in disease of the gallbladder is not known, but spasm and elevation of the diaphragm, shallow breathing caused by morphine and the recumbent posture, aspiration of infected material and spread of the infection from the gallbladder by way of the lymphatics into the blood stream and thus to the lungs are probably the chief inciting factors. The usual interval between the colic and the pneumonia was two to six days, the pneumonia was characterized by a relatively benign course and paucity of cough and expectoration. Treatment should be directed toward the condition that constitutes the most serious threat to the patient's life, usually it is the pneumonia. Deep breathing, use of carbon dioxide oxygen, frequent change of position and a decrease in the use of morphine particularly immediately after cholecystectomy, may prevent this complication.

**Sulfonamides for Tonsillitis**—Hopkins gave sulfanilamide or sulfapyridine to 12 patients with acute rheumatic fever and to 49 with tonsillitis due to the hemolytic streptococcus. None of the patients with rheumatic fever had any beneficial effect from either drug. Their use was not followed by any fall of temperature, polyarthritides was not relieved and carditis was not prevented. Most patients showed a degree of exanthesis. Leukopenia did not develop, in fact the leukocyte count tended to rise rather than to fall. The patients with streptococcal tonsillitis did not receive any beneficial effect from the use of the drugs. Compared with a control group of patients the period of pyrexia, the duration or severity of the local manifestations or the period of hospitalization was not shortened. Complications were more frequent in the treated group than in the control group. Two patients undergoing intensive treatment with sulfapyridine acquired streptococcal tonsillitis. The carrier state was not influenced by the drugs.

**Epidemic Myalgia Affecting Muscles of Neck**—A "stiff neck" seemed prevalent in parts of southern England during the summer and fall of 1941; a study of two months was carried out on 163 workers in a piston ring factory. Beeson and Scott obtained a history of pain or stiffness in the neck or shoulder from 29 of the workers, 12 men and 17 women. Although the disease was usually mild, some workers were incapacitated for two weeks or longer. The clinical features were unlike those of Bornholm disease but resembled those of acute fibrositis. The authors hope to direct attention to the occurrence of the syndrome in epidemic form.

**Diagnosis of Clostridium Welchii Infection**—In the cervical smears of 20 women with severe Clostridium welchii infection following abortion, Butler found many heavily capsulated bacilli and considerable damage to leukocytes. In 64 similar patients in whom a severe Clostridium welchii infection did not develop, this combination was not seen.

**Agglutinin Inhibiting Substance in Human Serum**—The conclusion that high titer universal donor blood is dangerous seems to be drawn chiefly by inference, as Aubert and his collaborators point out that there are practically no recorded facts directly incriminating the donor's agglutinins. Usually when a hemolytic reaction occurs the donor's titer has not been determined and it has never been shown that it was the recipient's and not the donor's cells which were hemolyzed. It seems that the question can be answered only by observing the effects of a deliberate injection of high titer isoagglutinins. Preliminary results of such a study suggest that donor isoagglutinins are but rarely the cause of a hemolytic transfusion reaction.

**Sulfapyridine for Pulmonary Tuberculosis**—According to Ellman and his colleagues, 47 of 89 patients with advanced tuberculosis with a grave prognosis were given sulfapyridine. The patients were kept at complete rest until they had been afebrile four weeks. Sulfapyridine was administered in doses of 0.5 Gm four times a day for four days a week throughout the period of hospitalization. Vomiting was the only complication. Of the 47 treated patients, 25 died, the condition of 3 was unaltered, in 3 it was slightly improved, in 3 it was quiescent, and 13 patients became ambulant. Of the 42 control patients, 26 died, 3 became worse, 8 became ambulant, the condition of 1 was unaltered and in 4 it was slightly improved. The drug showed a higher rate of recovery among patients who had the disease in slightly or moderately severe form. Tubercle bacilli disappeared more frequently from the treated group but contrary to expectations pyogenic organisms were not affected by the drug. The concentration of sulfapyridine in the sputum is a guide to the efficacy of treatment, when high the patient's condition is correspondingly improved. Patients severely affected with the disease showed no improvement.

**Anais Brasileiros de Ginecologia, Rio de Janeiro****13 1-88 (Jan) 1942 Partial Index****\*Missed Abortion from Bouba** Ferreira dos Santos—p 20

**Missed Abortion from Bouba**—Ferreira dos Santos reports a case in which bouba developed early in the course of pregnancy. Shortly after the disease appeared the size of the uterus diminished. By the end of the seventh month of pregnancy the patient was of normal appearance. Later she eliminated a mummified fetus. The author believes that bouba was the etiologic factor of the missed abortion.

**Ana d D Púb Nac p Enf d Ap Dig, Buenos Aires****4 1-926 (Dec 31) 1941 Partial Index****\*Therapy of Acute Hemorrhages from Gastric and Duodenal Ulcers** C Bonorino Udaondo—p 231

**Therapy of Acute Hemorrhage from Gastric and Duodenal Ulcers**—Bonorino Udaondo reports 646 cases of gastric or duodenal ulcer in which the diagnosis was verified by roentgenoscopy, gastroscopy or surgical intervention. Acute hemorrhage occurred in 73 cases and recurred in 17. Medical therapy is indicated during the bleeding in all cases regardless of whether it is subacute, acute, primary or recurrent as well as regardless of the age. The patient is put to bed and an ice bag is applied to the epigastrium not to control the bleeding but to keep him quiet. No food, water or drugs are given by mouth during the first forty-eight hours. Morphine, atropine, pantopon (the hydrochlorides of the alkaloids of opium, principally morphine), intravenous injections of a 5 or 10 per cent solution of calcium chloride or calcium lactate, transfusions of 200 or 250 cc of blood and intravenous or subcutaneous injections of saline solution by the drop method are given during the first three to four days. Feeding is gradually resumed after forty-eight hours of continued diminution of hemorrhage. Enemas are of importance in preventing hyperazotemia, which is an aggravating factor in the prognosis of patients about to be operated on. Patients are kept in bed on a strict diet as long as occult hemorrhage persists. As a rule, occult bleeding disappears within ten to fifteen days. Patients leave the bed by the third or fourth week. Iron or liver is administered for the control of secondary anemia. Treatment is continued after the disappearance of the clinical symptoms and x-ray signs until a cure is accomplished. Partial gastrectomy is indicated for hemorrhages recurring at short intervals. The operation is performed one month after the last hemorrhage.

**Archivos Arg de Enf del Ap Digest, Buenos Aires****17 119-334 (Dec-Jan) 1941-1942 Partial Index****\*Megacolon and Its Modern Conception** E Etzel—p 123

Megacolon and Simultaneous Megadiaphragm E G Murray and E A Petrolí—p 298

**\*Hypothalamus and Megacolon** F Vidal—p 310

**Megacolon**—According to Etzel, acquired megacolon is a disorder caused by achalasia of one or more sphincters of the large intestine. In the majority of the cases achalasia is localized in the sphincters of the terminal segment of the colon and the rectum. The achalasia is the result of destruction of the plexus of Auerbach at the level of the sphincter. Megacolon is a symptom of a disorder of the intramural autonomic nervous system. Other manifestations of this disorder are megaesophagus, achalasia of the pylorus, megaloureter, megabladder, alterations in the electrocardiogram, polyneuritis, achlorhydria and lowered basal metabolism. A chronic alimentary deficiency, most probably in vitamin B<sub>1</sub>, is most likely the factor involved. Surgical treatment of the megalocolon should aim to overcome the achalasia of the sphincter. Partial resection of the sphincter is the most logical operation. It is not the ideal operation for the pelvic rectal sphincter. Administration of thiamine hydrochloride does not cure megacolon, but it can restrict the lesions.

The prophylaxis of megacolon by a balanced diet must be the aim of therapy. Congenital megacolon differs from an acquired one and is associated with an abnormal development of Auerbach's plexus at the level of the involved sphincter.

**Hypothalamus and Megacolon**—Reports from the literature suggest that the hypothalamus exerts great influence on the visceral activity. Vidal destroyed in 4 male rats the medial preoptic area, the lateral hypothalamus (pars tuberalis), pars mammillaris hypothalami and fibers of the supramammillary commissure by means of a unipolar electrode of the modified Horsley-Clarke apparatus and observed after several weeks the development of a megacolon.

**Repertorio de Medicina y Cirugía, Bogotá****2 1-82 (Jan 15) 1942 Partial Index****\*Postoperative Tetanus** G Guerrero Izquierdo—p 57

**Postoperative Tetanus**—Guerrero Izquierdo reports postoperative tetanus in two persons who came from a rural district and had been operated on, one for talipes and the other for removal of a bullet from the deltoid muscle. Both were treated with intraspinal injections of tetanus antitoxin and both got well. He believes that latent tetanus bacilli may exist in the intestine of many normal persons, in noninfected war wounds and postoperative wounds in the course of healing and in scars. Latent tetanus bacilli are more frequent and more virulent in persons in rural districts. The virulization of tetanus bacilli and consequent development of tetanus depend on the diminution of the local resistance resulting from local trauma and contamination of the tissues or from general bacterial infection. Postoperative tetanus is more frequent after operations on the digestive tract. Contamination of the wound by tetanus bacilli from the intestine takes place by way of the lymphatics. When tetanus develops after operations in areas at a distance from the digestive tract it is caused by bacilli dormant in the scars. War wounds and operative wounds in the course of healing harbor tetanus bacilli in 20 per cent of the cases. Tetanus does not develop in these cases unless there is an associated bacterial infection. The general condition in these cases may be grave and out of proportion to the local wound, which is apparently benign.

**Revista Médica Cubana, Havana****52 1131-1224 (Dec) 1941 Partial Index****\*Transitional Forms Between Lymphosarcoma and Chronic Lymphatic Leukemia** N Puente Duany and F Lopez Fernandez—p 1131

**Transitional Forms Between Lymphosarcoma and Chronic Lymphatic Leukemia**—Puente Duany and Lopez Fernandez report 5 cases of an afebrile diffuse adenopathy in patients between the ages of 47 and 70 years. The disease suggested a diffuse lymphosarcoma or an atypical chronic lymphatic aleukemia. The adenopathy first appeared either in the cervical, axillary or inguinal nodes. The enlargement was excessive. Other groups of superficial and deep lymph nodes became moderately enlarged in the course of the disease. In one group of patients mobility, consistency and appearance of the adenopathy were of the type of chronic lymphatic leukemia. There was a moderate leukocytosis and lymphocytosis. A myelogram showed lymphoid infiltration of the sternal bone marrow and diffuse, cutaneous, erythematous lesions or infiltration. Later in the course of the disease, moderate enlargement of the liver and the spleen occurred. In the other group the adenopathy was of the type observed in lymphosarcoma. The blood, sternal bone marrow and skin were normal. There was neither hepatomegaly nor splenomegaly all through the disease which was more acute and rapid than the leukemic variety. The period of the development of the adenopathy without clinical symptoms amounted to from two to four months for the lymphosarcomatous type and to one to two years for the leukemic type. The general condition of the patients was normal a long time but was followed by a rapid deterioration in the advanced stage. Biopsy of lymph nodes in both groups showed changes of the type of a chronic lymphoid leukemia. Perforation of the enlarged nodes reduced their volume.

reduction was more evident in the leukemic variety. The clinical symptoms were not influenced by roentgen irradiation. The span of life was one and one half years in patients with the lymphosarcomatous type of the disease. Four patients are still living three to six years after the onset of the disease. The author believes that the two varieties are atypical forms of a diffuse lymphosarcoma and chronic lymphatic leukemia and that they represent transitional forms between lymphosarcoma and chronic lymphatic leukemia.

### Revista Medica Latino-Americana, Buenos Aires

27 341-436 (Jan) 1942

\*Pulmonary Abscess and Tuberculosis—A. A. Ramondi and R. Scar-  
tazzini—p. 331

Granulomatous Hematoderma—M. Manguel—p. 375

Cranio-cervical Hematoderma—A. Zavala Saenz—p. 380

Tuberculin Patch Test—Vollmer—M. E. Pastor and R. E. Lempere  
—p. 396

**Pulmonary Abscess and Tuberculosis**—Ramondi and Scartazzini point out the desirability of differentiating between cases of pulmonary abscess in which tuberculosis develops and cases of tuberculosis in which abscess develops. The first group is much more frequent. The local factor tends to direct the action of the focus of suppuration on the old latent and inactive lesions by progression and extension. It comes in contact with a tuberculous focus which for a long time has been encapsulated and inactive. The bacilli thus liberated produce distinct lesions. If the dissemination is intracranial the foci localize near the abscess; if the dissemination is hematogenic generalized or circumscribed military lesions are produced. The bacilli may be expectorated from the bronchi without colonization taking place. All conditions likely to upset the equilibrium can produce activity in an old tuberculous lesion which had been kept inactive by the defensive powers of the organism. Thus suppuration involving a considerable part of the lung can be the cause of a tuberculous exacerbation as a consequence of a profound alteration of the general state. The second group (cases of tuberculosis in which an abscess develops) has a low frequency. Tuberculous tissue is refractory to pyogenic or putrefactive flora of a complicating abscess. The treatment must take into account the clinicopathogenic classification of the concurrence of pulmonary abscess and tuberculosis. In view of the relative frequency of tuberculous complications in cases of pulmonary abscess they advise early treatment with the object of preventing the development of this complication. In the rare cases in which abscess complicates tuberculosis they recommend measures employed in the different types. Active surgical treatment is contraindicated in the rare case in which the abscess complicates the tuberculous lesion, even simple drainage is not without danger. In cases in which the abscess is in the healthy pulmonary tissue, the decision whether the treatment should be surgical or not is dependent on the behavior of the tuberculous lesion.

**Granulomatous Hematoderma**—Zavala Saenz reports 2 cases. A woman aged 23 has symmetrical circinate erythematous spots "urticarious" and chronic in character and a man aged 36, whose cutaneous disorder began at the age of 16, presents erythematous pigmented patches and soft tumors of various sizes, some of which are ulcerated. Both patients are constantly troubled with pruritus. The similarity of the observed lesions with those encountered in parakeratosis, psoriasis, urticaria pigmentosa, certain forms of prurigo, neurodermatitis mycosis fungoides, erythema perstans and chronic multianular erythema of Darier suggests that all these incurable diseases of the skin have a common etiology the cause of which can be found in the disease of the leukopoietic system. The schematic table of Weissenbach and Basch reproduced in this article, indicates this etiologic relationship, which, if once established, permits appropriate treatment of a number of cutaneous disorders that heretofore could be treated only in an empiric manner, which in many cases proved ineffective. The 2 cases described are regarded as manifestations of granulomatous hematoderma in different stages of development.

Continuous Oral Drip in Diseases in Infants—G. A. Estrada—p. 466

**Continuous Oral Drip**—Estrada directs attention to the difficulties of administering food and fluids to sick infants. He invented a mouth mask which is maintained in place by means of two pieces of tape tied at the back of the neck. It is made of semidur rubber with a transverse oval hole for the mouth and a small lateral perforation to correspond to the commissure of the lips for the passage of 3 or 4 centimeters of an end of a Nelaton catheter. The latter is fixed at this point to the mask with adhesive tape. Its other end is connected to the tube of a common irrigator which contains the fluid or food. The free end of the catheter is placed between the cheek and the gum of the infant's mouth when the mask is applied. The tube of the irrigator is provided with a clamp by which the flow of the fluid or food is regulated. The fluid drips slowly drop by drop at regular intervals into the infant's mouth.

Androgen in Therapy of Hypertrophy of Thymus in Infants—C. A. Urquijo—p. 434

**Androgen in Therapy of Hypertrophy of Thymus**—Urquijo reports 2 cases of hypertrophy of the thymus in infants 6 and 11 months of age. The diagnosis was verified by roentgen demonstration of an enlarged thymus shadow. One of the patients was given six injections of 15 mg. of testosterone propionate at one day intervals. The other was given injections of androgen which corresponded to 5 Gm. of fresh testicle. The thymus shadow disappeared from the roentgenograms, and the general condition of the patients improved.

Study of Pneumococcal Peritonitis—Velocity of Sedimentation as Differential Diagnostic Key with Appendicitis—L. Torres Marty—p. 382

Treatment of Pernicious Anemia—E. Arias Vallejo—p. 386

**Treatment of Ozena**—Calderin and Larru Fernandez advance a theory of ozena. They believe the atrophy to be the result of a neuritis of the trigeminus by a descending or an ascending process which attacks the ethmoidal fibers of the nasociliary branch of the ophthalmic nerve or of the sphenopalatine nerve. These types of neuritis require for their development (1) a constitutional factor (2) general or local toxic or traumatic agents such as syphilis, tuberculosis or scleroma and locally chronic catarrhs, pyorrhinitis, adenoid vegetations and all local traumatism and alimentary insufficiency or inadequate utilization of vitamins, (3) endocrine dysfunction. The infection and the resulting odor are produced secondarily by the implantation of a rhinophilic organism (Perez, Loewenberg, Abel, Belfanti, Della Vedova, Pes Gradenigo and the like) on a trophically changed mucosa with thick and deficient secretion, the stagnation and putrefaction of which behind the nasal fossa are favored by a physiologically anarchic respiration which transforms it into an excellent culture medium for bacteria. The authors consider it necessary to influence the sympathetic in its action on the nasal fossa, thereby producing more lasting results. Two points are decisive in the treatment (1) reducing the caliber of the abnormally wide and atrophic nasal fossa, (2) modifying the nasal sympathetic in order to correct the trophic action. Barium oxide in petrolatum is injected into the nasal fossa, and this is combined with roentgen therapy of the cervical region. There is no advantage in applying roentgen rays to lateral cervical fields, it is much more simple and rapid to resort to a frontal attack. This form of roentgen therapy has proved harmless. The irradiation was of medium penetration so as to stimulate the peripheral sympathetic. The caliber of the nasal fossa responded in the desired manner. The author is investigating the possibility of combining this treatment with the administration of sulfanilamide with or without the pyridine group because of the action of these substances on cocci including probably the rhinophilic organisms which cause the fetor.

**Anais Brasileiros de Ginecologia, Rio de Janeiro****13 1-88 (Jan) 1942 Partial Index****\*Missed Abortion from Boubá—Ferreira dos Santos—p 20**

**Missed Abortion from Boubá**—Ferreira dos Santos reports a case in which boubá developed early in the course of pregnancy. Shortly after the disease appeared the size of the uterus diminished. By the end of the seventh month of pregnancy the patient was of normal appearance. Later she eliminated a mummified fetus. The author believes that boubá was the etiologic factor of the missed abortion.

**Therapy of Acute Hemorrhage from Gastric and Duodenal Ulcers**—Bonorino Udaondo reports 646 cases of gastric or duodenal ulcer in which the diagnosis was verified by roentgenoscopy, gastroscopy or surgical intervention. Acute hemorrhage occurred in 73 cases and recurred in 17. Medical therapy is indicated during the bleeding in all cases regardless of whether it is subacute, acute, primary or recurrent as well as regardless of the age. The patient is put to bed and an ice bag is applied to the epigastrium not to control the bleeding but to keep him quiet. No food, water or drugs are given by mouth during the first forty-eight hours. Morphine, atropine, pantopon (the hydrochlorides of the alkaloids of opium, principally morphine), intravenous injections of a 5 or 10 per cent solution of calcium chloride or calcium lactate, transfusions of 200 or 250 cc of blood and intravenous or subcutaneous injections of saline solution by the drop method are given during the first three to four days. Feeding is gradually resumed after forty-eight hours of continued diminution of hemorrhage. Enemas are of importance in preventing hyperazotemia, which is an aggravating factor in the prognosis of patients about to be operated on. Patients are kept in bed on a strict diet as long as occult hemorrhage persists. As a rule, occult bleeding disappears within ten to fifteen days. Patients leave the bed by the third or fourth week. Iron or liver is administered for the control of secondary anemia. Treatment is continued after the disappearance of the clinical symptoms and x-ray signs until a cure is accomplished. Partial gastrectomy is indicated for hemorrhages recurring at short intervals. The operation is performed one month after the last hemorrhage.

**Megacolon**—According to Etzel, acquired megacolon is a disorder caused by achalasia of one or more sphincters of the large intestine. In the majority of the cases achalasia is localized in the sphincters of the terminal segment of the colon and the rectum. The achalasia is the result of destruction of the plexus of Auerbach at the level of the sphincter. Megacolon is a symptom of a disorder of the intramural autonomic nervous system. Other manifestations of this disorder are megaesophagus, achalasia of the pylorus, megaloureter, megabladder, alterations in the electrocardiogram, polyneuritis, achlorhydria and lowered basal metabolism. A chronic alimentary deficiency, most probably in vitamin B<sub>1</sub>, is most likely the factor involved. Surgical treatment of the megalocolon should aim to overcome the achalasia of the sphincter. Partial resection of the sphincter is the most logical operation. It is not the ideal operation for the pelvic rectal sphincter. Administration of thiamine hydrochloride does not cure megacolon, but it can restrict the lesions.

The prophylaxis of megacolon by a balanced diet must be the aim of therapy. Congenital megacolon differs from an acquired one and is associated with an abnormal development of Auerbach's plexus at the level of the involved sphincter.

**Hypothalamus and Megacolon**—Reports from the literature suggest that the hypothalamus exerts great influence on the visceral activity. Vidal destroyed in 4 male rats the medial preoptic area, the lateral hypothalamus (pars tuberalis), pars mamillaris hypothalami and fibers of the supramamillary commissure by means of a unipolar electrode of the modified Horsley-Clarke apparatus and observed after several weeks the development of a megacolon.

**Repertorio de Medicina y Cirugía, Bogotá****2 1-82 (Jan 15) 1942 Partial Index****\*Postoperative Tetanus—G Guerrero Izquierdo—p 57**

**Postoperative Tetanus**—Guerrero Izquierdo reports postoperative tetanus in two persons who came from a rural district and had been operated on, one for talipes and the other for removal of a bullet from the deltoid muscle. Both were treated with intraspinal injections of tetanus antitoxin and both got well. He believes that latent tetanus bacilli may exist in the intestine of many normal persons, in noninfected war wounds and postoperative wounds in the course of healing and in scars. Latent tetanus bacilli are more frequent and more virulent in persons in rural districts. The virulization of tetanus bacilli and consequent development of tetanus depend on the diminution of the local resistance resulting from local trauma and contamination of the tissues or from general bacterial infection. Postoperative tetanus is more frequent after operations on the digestive tract. Contamination of the wound by tetanus bacilli from the intestine takes place by way of the lymphatics. When tetanus develops after operations in areas at a distance from the digestive tract it is caused by bacilli dormant in the scars. War wounds and operative wounds in the course of healing harbor tetanus bacilli in 20 per cent of the cases. Tetanus does not develop in these cases unless there is an associated bacterial infection. The general condition in these cases may be grave and out of proportion to the local wound, which is apparently benign.

**Revista Médica Cubana, Havana****52 1131-1224 (Dec) 1941 Partial Index****\*Transitional Forms Between Lymphosarcoma and Chronic Lymphatic Leukemia—N Puente Duany and F Lopez Fernandez—p 1131**

**Transitional Forms Between Lymphosarcoma and Chronic Lymphatic Leukemia**—Puente Duany and Lopez Fernandez report 5 cases of an afebrile diffuse adenopathy in patients between the ages of 47 and 70 years. The disease suggested a diffuse lymphosarcoma or an atypical chronic lymphatic aleukemia. The adenopathy first appeared either in the cervical, axillary or inguinal nodes. The enlargement was excessive. Other groups of superficial and deep lymph nodes became moderately enlarged in the course of the disease. In one group of patients mobility, consistency and appearance of the adenopathy were of the type of chronic lymphatic leukemia. There was a moderate leukocytosis and lymphocytosis. A myelogram showed lymphoid infiltration of the sternal bone marrow and diffuse, cutaneous, erythematous lesions or infiltration. Later in the course of the disease, moderate enlargement of the liver and the spleen occurred. In the other group the adenopathy was of the type observed in lymphosarcoma. The blood, sternal bone marrow and skin were normal. There was neither hepatomegaly nor splenomegaly all through the disease, which was more acute and rapid than the leukemic variety. The period of the development of the adenopathy without clinical symptoms amounted to from two to four months for the lymphosarcomatous type and to one to two years for the leukemic type. The general condition of the patients was fairly advanced stage. Biopsy of lymph nodes in both groups showed changes of the type of a chronic lymphoid leukemia. Re-irradiation of the enlarged nodes reduced their volume.

## Book Notices

*Psychiatry in Medical Education* By Franklin C. Lbaugh, M.D. Professor of Psychiatry, University of Colorado School of Medicine, Denver, and Charles A. Lyster, M.D., Associate Professor of Psychiatry, University of Colorado School of Medicine. Cloth. Price \$3.00. Pp. 119. New York: Commonwealth Fund, Ltd. London: Oxford University Press, 1941.

The development of psychiatry during the time which has elapsed since the first world war has been little short of phenomenal. From an isolated specialty limited almost entirely to the walls of the mental hospital or the courtroom it has grown into a large field of medicine closely related to internal medicine, surgery and the other specialties. It has emphasized the preventive aspects through child guidance and mental hygiene clinics, has invaded industry, the schools and correctional institutions and now numbers as well many practitioners in private practice.

The present volume records fully the corresponding developments which have taken place in the teaching of psychiatry in medical schools and in the postgraduate period. Great strides have been made, fostered and encouraged by the Commonwealth Fund, the Rockefeller Foundation, the National Committee for Mental Hygiene and the American Psychiatric Association. In this development Dr. Lbaugh has had a conspicuous part and he has visited nearly every medical school in the United States as a part of his long connection with the work. The present volume contains valuable data not only on the actual presentation of psychiatry in the medical curriculum but also on the teaching activities of the numerous psychiatric hospitals and on the opportunities for postgraduate education whether for the general practitioner or for the specialist.

A large volume which is essentially factual can hardly be abstracted in a review. One is impressed, however, with the painstaking work done in assembling the data and in the progress which the book records as having been made in the past decade. Obviously much yet remains to be done but the dean and the head of the department of psychiatry have here a ready reference work whereby they may compare themselves with their fellows and gather inspiration for further improvement. In general the teaching of psychiatry has passed the dry-as-dust stage; it is now the presentation of a living subject, with relationships to the other fields of medicine and with interests for the future general practitioners. The authors emphasize three fundamental principles which should be followed by the student of psychiatry: (1) the concept of man as a whole, (2) the concept of man as a living being in action—that mental disorders in short have a natural history, and (3) the close relationship of psychiatry to medicine in general. Psychosomatic medicine is going to be the focus of emphasis in psychiatry, and we must constantly stress the importance of emotional factors in disease. (p. 508)

The general orientation of the book is strictly meyerian and the experience of the institution with which both authors are associated is perhaps unduly emphasized. The volume will, however, meet enthusiastic and general approbation as a valuable compilation of data in a rapidly growing field and as an indicator of the directions of further progress.

*Die Ursachen der Entstehung des Kropfes (Struma) und seiner Formen bei Mensch und Tier mit Ausblicken auf rationelle Prophylaxe und Heilung. Deduktive und synthetisch experimentelle Studien über die Variationen des thyreothymischen Systems der Vertebraten und des Menschen unter dem Einfluss der Umwelt.* Von Dr. et Dr. h. c. Joh. Ulrich Duerst, o. Professor der Hygiene und Zootechnik an der vet. med. Fakultät der Universität Bern. Cloth. Price 14.40 marks. 24 Swiss francs. Pp. 538 with 82 illustrations. Berne: Hans Huber, 1941.

Duerst's foundation for this monograph rests on thirty-two years of experience with goiter in domestic animals together with his close association with such able students of goiter as the late Theodor Kocher, de Quervain and Wegelin. The book is divided into four parts. Part I deals with the comparative embryology and anatomy of the thyrothymic system of vertebrates. Part II deals with the physiology of the thyroid and thymus glands as it is influenced by constitutional, conditional and environmental factors. Part III deals with terrestrial

factors (air, water, soil, climate), their variations and actions on the thyrothymic system. Part IV discusses goiter development in man. Each of these parts is divided into four or more chapters. Thus part III contains four chapters dealing with (1) air, (2) climate, (3) water and (4) composition of the earth's crust as bearing on the problem of thyroid physiology and pathology. Throughout the book stress is continually laid on the importance of the compensating activities of the thyroid and thymus glands in connection with the internal and external variations in the oxygen and carbon dioxide volumes and pressures. For example, he thinks that goiter, especially in domestic animals, is much more dependent on deficient oxygen together with an excess of carbon dioxide than on the administration of goiter-producing foods. The importance of excess calcium and magnesium and of deficiencies of iodine and many other mineral imbalances is fully accepted and their possible relation to oxidation and carbon dioxide variations is discussed. The relation of oxygen deficiency and of temperature to thyroid activity is well established but the relation of carbon dioxide to thymic activity as outlined by the author involves much speculation and sidesteps such thymic reactions as are seen in toxic diffuse goiter and Addison's disease. Probably a fourth of the book is devoted to a discussion of the thyrothymic system, and other thymic interrelations are neglected. To the reviewer, however, the thymus at least in its objective manifestations appears to be more related to the steroid hormones than to the thyroid. One could also ask for proof that colloid and parenchymatous goiters are different kinds of goiter. However, interwoven in this extensive discussion the known facts associated with endemic goiter are fully presented. Each chapter concludes with a summary which conveniently reduces an extensive and often speculative discussion to simple statements. Also there is appended an extensive bibliography arranged alphabetically for each chapter.

*Contributions to Embryology, Volume XXIX, Nos. 179 to 186.* Carnegie Institution of Washington Publication 525. Paper. Pp. 193 with illustrations. Washington, D. C., 1941.

*Embryology of the Rhesus Monkey (Macaca mulatta).* Collected Papers from the Contributions to Embryology. Published by the Carnegie Institution of Washington. Carnegie Institution of Washington Publication 538. Paper. Price \$1. Various pagination with illustrations. Washington, D. C., 1941.

The current volume of the Contributions to Embryology contains several studies which are landmarks in primate embryology. Hertig and Rock describe two ova 11 and 12 days of age, the former is undoubtedly the youngest human embryo yet described. Both specimens are beautifully illustrated in photomicrographs. Of similar importance is the paper of Heuser and Streeter dealing with the development of macaque embryos. The abundance of specimens that have become available through the use of the monkey for such investigations is a testimonial to the scientists associated with the Carnegie Laboratory. Heuser and Streeter had more than fifty-five ova aged 8 to 13 days available for study of the early stages. Both Hertig and Rock for man and Heuser and Streeter for the monkey derive the primitive mesoblast by delamination from the cytotrophoblast. Before this new concept can be accepted adequate cytologic studies of the alleged transformation are necessary. The paper of Schultz on the growth and development of the orang-utan is a substantial contribution of interest particularly to physical anthropologists. A human embryo in the primitive streak stage is described by Jones and Brewer and some new features of the adrenal blood supply are elucidated by Gersh and Grollman. The paper of Krafka unfortunately falls below the level set by the other contributions to this substantial volume. Krafka is largely concerned with the histology of the endometrium associated with a presomite embryo and is guilty of numerous errors. Several of his citations as for example from Bartelmez's contributions to the histology of the menstruating uterus are inaccurate or misleading; he further confuses the premenstrual and the menstrual states and uncritically describes obvious artefacts. The Carnegie Institution has collected and issued as a separate volume a series of papers dealing with the embryology of the rhesus monkey. In addition to the paper of Heuser and Streeter it contains studies dealing with the maturation of the ovum, tubal ova and placentation.

**Psychosurgery Intelligence, Emotion and Social Behavior Following Prefrontal Lobotomy for Mental Disorders** By Walter Freeman, M.D., Ph.D. F.A.C.P., Professor of Neurology, George Washington University, Washington, D.C. and James W. Watts B.S., M.D., F.A.C.S., Associate Clinical Professor of Neurosurgery, George Washington University. With Special Psychometric and Personality Profile Studies By Thelma Hunt M.D., Ph.D., Associate Professor of Psychology, George Washington University. Fabrikoid Press, \$6 Pp 337 with 81 illustrations Springfield, Illinois & Baltimore Charles C Thomas Publisher, 1942

Here is a book which admirably achieves its purpose. The two physicians who first in September 1936 introduced frontal lobotomy for the treatment of certain mental disorders into the western hemisphere have set forth their technique and experiences. It is not the purpose of this review to consider the merits of frontal lobotomy. That is a matter which the medical profession must ultimately decide after a careful weighing of all available data. In this clear and concise monograph the authors have first briefly related the history both of other cerebral operations for the relief of psychotic states and of frontal lobotomy. They have then discussed the structure and functions of the frontal lobes and the manifestations of destructive lesions of the frontal lobes as revealed by animal experimentation, and in human cases by tumors, atrophies, vascular disorders, injuries and extirpations. With great clarity they have then discussed how a frontal lobotomy is made, and the results of this operation on the patient. With commendable frankness the authors have presented the complications and disadvantageous results of the operation which they have encountered as well as the beneficial ones. The effect of the procedure on various types of mental disorder is then taken up in detail. The authors are obviously enthusiastic proponents of this procedure, and more unfavorable criticism must be sought from others. At times it appears that their enthusiasm may have been excessive, and one cannot but wonder at the advisability of having an alcoholic lawyer who has been separated from much of his frontal lobes "returned to a position in the government service," where he "at present is employed in highly technical work" (p. 110). In fact some readers may be suspicious that other government officials in Washington may have fallen into the authors' hands. There are a full bibliography and useful index.

**Endotracheal Anaesthesia** By Noel A. Gillespie D.M. B.Ch. M.A., Research Associate and Resident in Anaesthesia, University of Wisconsin. Madison Cloth Price \$4 Pp 187 with 45 illustrations. Madison University of Wisconsin Press, 1941

This book is timely, since it deals in detail with one of the most valuable methods of inhalation anesthesia, the endotracheal method. The interesting history of endotracheal anesthesia is presented, as well as the advantages and disadvantages of the method. Some of the various available types of equipment are illustrated. The technique of oral as well as nasal intubation is described and illustrated in considerable detail. The practical application of the method is discussed, as well as the sequelae that occasionally are associated with the use of the method. The subject of therapeutic intubation other than for anesthesia is touched on briefly. Every active anesthetist will want to read this book, for it represents the most effective means of advancing the specialty, namely, that a competent person will present in considerable detail the technique of some definite method of anesthesia. It is to be hoped that the author will produce more monographs of this type on other subjects.

**Nasal Sinuses An Anatomic and Clinical Consideration** By O. E. Van Alstyne M.D. Assistant Professor Department of Laryngology, Rhinology and Otolaryngology, University of Illinois College of Medicine, Chicago. Cloth Price, \$6.50 Pp 262 with 83 illustrations. Baltimore William Wood & Company 1942

The author has limited his discussion on the nasal accessory sinuses to anatomic and clinical aspects. In the portion devoted to anatomic considerations he has done unusually well, and any one from medical student to experienced rhinologist can derive much of value from a careful study of this part of the text. It is based on the author's own extensive dissections over a period of ten years. The illustrations are numerous and well done, and because they are original they have a freshness and absence of the familiar which makes their study a combined pleasure and benefit.

The diagnostic and therapeutic considerations are abbreviated but not lacking in valuable content. It is apparent that they represent the mature judgment of a clinician of conservative

tendencies whose opinions have been influenced not only by well grounded anatomic knowledge but by a sympathetic understanding of the healthy physiologic advances that have taken place in the past decade or so in the field of rhinology. For this reason there is not in this work the usual detailed but frequently uncritical discussion of operative procedures, minor and major, so often noted in many standard textbooks on rhinology.

The experienced specialist in this field can turn to this creditable discussion with anticipation, pleasure and benefit and a good deal of pride that scholarly work based on the fundamental disciplines of anatomy and physiology continues to emanate from the ranks of active clinicians.

**Methods of Treatment in Postencephalitic Parkinsonism** By Henry D. von Witzleben. Preface by Theodore J. C. von Storch. Associate Professor of Neurology, Albany Medical College, Albany. Cloth Price \$7.50 Pp 164 New York Grune & Stratton, 1942

This is an admirable book dealing competently with a subject of practical and theoretical importance. There is an assemblage of all the pertinent literature, a careful consideration of the main aspects of differential diagnosis, perhaps more clearly developed in this book than elsewhere. The rest of the book is devoted to various types of treatment, those which have been tried and found wanting and those which have given some help to the patient. Like every other more or less hopeless disease, the postencephalitic Parkinson's syndrome has been attacked in a dozen directions by chemotherapy, brain surgery, vaccine and a large variety of drugs. The author clearly reviews these attempts, and, while he seems to give more value to the so-called Bulgarian treatment than it merits, his account is nevertheless clear and on the whole fair.

**How to Organize Group Health Plans** By Martin W. Brown, LL.D. Katharine G. Clark and Perry R. Taylor. Joint Committee of the Twentieth Century Fund and the Good Will Fund, and Medical Administration Service Inc. Paper Price 25 cents Pp 72 Boston Edward A. Filene Good Will Fund, Inc. 1942

After a mention of other types of organized medical care, attention is centered on contract group plans. There is a legal argument (not very convincing) trying to show that recent court decisions have cleared the way for corporations to practice medicine with instructions on how to draw up a charter that will conform to the law as the authors interpret it. Some helpful suggestions about avoiding "bad risks" in securing members is followed by a chapter on methods of enrolment which contains warnings against infringing the principles of medical ethics concerning advertising while conducting "publicity" and "educational" campaigns to secure subscribers. It is recognized that "astute management of varied factors is necessary" if the suspicions of organized medicine are not to be aroused.

**Standardization Activities of National Technical and Trade Organizations** By Robert A. Martino. U.S. Department of Commerce National Bureau of Standards National Bureau of Standards Miscellaneous Publication M169. Cloth Price 75 cents Pp 288 Washington D.C. Supt. of Doc. Government Printing Office, 1941

The purpose of this practical book is well expressed in the preface. "This volume represents an effort to present an adequate picture of the standardization and simplification movement being carried on by national technical and trade organizations in the United States. It contains outlines of the activities and accomplishments of four hundred and fifty American societies and associations in which standardization is a major or an important activity." The contents of the volume will be of service not only to the approximate three thousand national and interstate organizations representing various industries and to commercial organizations and educational institutions.

**Modern Bread from the Viewpoint of Nutrition** By Henry C. Sherman and Constance S. Pearson. Cloth Price \$1.75 Pp 118 New York Macmillan Company 1942

Quite timely is this brief essay on modern bread from the point of view of nutrition. The book contains one hundred and four pages and slightly over twenty thousand words, discussing bread as a food, its proteins and vitamins, present trends and future problems. The concept is that enrichment of bread will give it even a more important place in the diet than it has had in the past. Indeed the authors say that bread "may now safely be utilized to supply as much as 40 per cent of the calories of the normal diet."

### TREATMENT OF GRANULOMA INGUINALE

To the Editor—A Negro woman aged 24 has had granuloma inguinale for five years. She has also active sickle cell anemia with a hemoglobin content of 40 to 50 per cent and jaundice barely detectable clinically. For the past two years she has been treated with antimony and potassium tartrate and fuadin after several injections of each drug. Jaundice is said to have appeared. Intravenous therapy with iodides and oral sulfadiazine therapy have been ineffectual; the latter resulting in hematuria. Please advise what is the best antimony compound to use, whether jaundice may be expected from its use and whether in this case the jaundice may have been coincidental with the sickle cell anemia. Also please advise in regard to alternative therapy if antimony is contra-indicated.

Paul Ally Kirschner, M.D., New York

ANSWER—The patient presents a complicated picture. The icterus might be concomitant with the sickle cell anemia since it is barely detectable clinically. Both antimony and potassium tartrate and fuadin have been employed in the treatment of granuloma inguinale but neither has been reported to produce icterus. True the effects of antimony on the system thought to a lesser extent resemble the effects following the use of arsenical compounds and it is well known that arsenic is hepatotropic.

The only compound of established value in the treatment of granuloma inguinale is some form of antimony and the best results are reported from the use of fuadin. The use of foreign protein therapy seems to be helpful at times but of course with a patient in the weakened condition of this patient one would hesitate to use too drastic measures of that type. One might employ injections of one of the milk compounds starting off with 3 cc given intramuscularly and gradually increasing the dose 2 cc at a time giving a dose twice a week for the foreign protein effect.

There seems to be no indication of value in the use of iodides and sulfonamide compounds for granuloma inguinale.

It is suggested that treatment with fuadin be begun again with an intramuscular dose of 25 cc which is to be gradually increased to 5 cc. The injections should be given once a week, one meanwhile watching the patient closely and checking on the icteric index.

If it is possible to employ surgical measures they might be considered. Some excellent results have been reported in the treatment of granuloma inguinale when the lesions have been amenable to total excision the edges being brought together with clips thereafter. Naturally if it is not possible to excise the entire area there will be a prompt recurrence.

### ARTIFICIAL INSEMINATION

To the Editor—I have a young woman patient whose husband is sterile. Repeated examinations have failed to show any spermatozoa either living or dead. The couple would very much like to have a baby. They would like to obtain one by artificial insemination. Could you tell how to go about such a procedure?

M.D. Montana

ANSWER—During the past few years much interest has been centered on artificial insemination, a donor's semen being utilized to overcome complete absence of sperm in a husband. Of course, great care must be exercised before undertaking such a procedure. From the physical side, the physician must convince himself that the husband has aspermia and that the wife has no abnormalities of the genitalia and that her tubes are patent. Furthermore, both husband and wife must be in excellent physical and mental condition and have negative Wassermann reactions. Both must give written consent to the procedure to absolve the physician from the possibility of a lawsuit. Furthermore, the written consent will act as a protection for the wife, the donor and the legal status of the child. Likewise, of great importance, is the selection of a proper donor. An individual must be chosen who bears a certain resemblance to the sterile husband not only racially and physically but also emotionally and temperamentally. For example, it might be embarrassing in later life if a tall blond, placid type of donor was selected for a short, swarthy highly emotional couple. Still more important, the physician must arrange for the collection of the donor's

semen and the insemination in such a way that the donor cannot possibly find out who is to receive his spermatozoa. Likewise, the recipient should not be able to discover who the donor is. There are many valid reasons for this chiefly the possibility of blackmail on the part of the donor and the risk of transference of affection from the recipient to the donor. To eliminate all risk the donor should be asked to bring his specimen to a different place from that in which the insemination is to be performed. If the specimen is to be delivered to the physician's office it must be brought to a side door during the physician's regular office hours when there are many patients, so that the donor could not possibly identify the recipient even if he watched every woman who left the office. Of course, the physician should use his judgment in selecting a donor who would not be so low morally as to resort to dishonesty.

In cases of artificial insemination in which a donor is used it is not necessary to use intrauterine insemination. All that is necessary is to deposit the sperm in the cervical canal or even at the external os. For this purpose a Luer syringe and cannula should be used but a glass pipet may suffice.

The technic of insemination is as follows. The patient is placed on the examining table, a speculum is inserted and the vagina and the external os are gently dried. There is no need to remove the secretion from the cervical canal unless it is purulent or unusually abundant. The semen is gently aspirated in the sterile syringe and the cannula attached. It is intracervical insemination is to be practiced, only a few drops of semen should be deposited in the cervical canal. The remainder should be placed at the external os after the speculum has been withdrawn. This can readily be accomplished by guiding the tip of the cannula with one finger in the vagina. If the semen is not to be placed in the cervical canal a few drops are placed at the external os and the remainder in the vaginal vault. Apparently it makes no difference in the results whether semen is deposited in the cervical canal or at the external os.

After the insemination, the patient's legs are stretched out on the examining table, her hips are elevated on a pillow and she is asked to remain in this position for about a half hour. Two or preferably three inseminations should be performed within seven days in the midinterval between two menstrual bleedings, at a time when ovulation is supposed to occur.

Further details concerning the technic may be found in the third edition of *Office Gynecology*, by J. P. Greenhill (Chicago, Year Book Publishers, 1940).

### CHANGED ROUTINE AND EFFICIENCY

To the Editor—My associates and I have had a considerable discussion as to whether the changing of a person's routine in his hours of work, sleep, recreation and meal times will affect his efficiency. We are much interested in knowing whether your organization has made a survey on the problem.

Walter Cappel, Milwaukee

ANSWER—Although this question cannot be answered categorically on the basis of crucial evidence, physiologic theory teaches that a change in habits of living impairs the efficiency of the majority of persons at least for a brief period. Kleitman (Sleep and Wakefulness, University of Chicago Press, 1939) examined the question in considerable detail. He found that many of the diurnal curves of performance coincide well with the diurnal curve of body temperature which is at a low ebb during the early morning hours. The existence of a diurnal curve of body temperature and performance is dependent chiefly on repeated performance since childhood and adherence to one's twenty-four hour routine of activities. The establishment of a new cycle is possible. However, a week or more is frequently required and some persons manifest a greater resistance to the development of a new cycle or routine of activities than others. Accordingly, it may be argued that alternating between a day and a night shift every week or two, as is done in some branches of the military services and in English industry, destroys any progress that has been made in the establishment of a new diurnal rhythm in body temperature and performance. Also according to theory, regular habits of work, play, meals, hours of retiring and awakening should be conducive to promoting the quality of sleep and the efficiency of work and deviations from the daily routine should be the exception rather than the rule. On the contrary, there are persons who have never been regular in their habits of living and have apparently become adapted to the irregularity of their lives. Whether they would become more efficient if they followed some routine is problematic. It is reported that most of the ship officers who make the trip to the Orient and back have become adapted to the changing diurnal conditions to which they are exposed. According to Vernon (Accidents and Their Prevention, Cambridge University Press, 1936) in England where it is the custom in

industry to reverse the day and night shifts at weekly intervals, it is seldom possible to detect the differences in health, productivity and accident liability between day and night shifts, if illumination is adequate. This is obviously not good evidence on which to base objection to physiologic theory, because the same group of persons is being observed under the same rather rapidly changing conditions, and it is possible that the day and night output are being equally impaired. The American system, in which the day and night shifts are not alternated weekly, conforms to physiologic theory. Apparently the theory has never been crucially tested by a long term experiment involving a large group of persons working in the same factory and doing the same type of work.

Irregularity of meals is commonly believed to predispose to digestive and gastric disorders. This notion was advanced as the reason for the high incidence of such disorders among the omnibus drivers in London (Hill, A. B. *Sickness of London Transport Workers*, London, His Majesty's Stationery Office, number 79, 1937). The cause of digestive and gastric disorders is not so simple. During the period in which the foregoing observation was made a "speeding up" of the London traffic routes was enforced which increased the nervous strain of the work. Environmental factors which cause irregularity in meals are probably more responsible for the functional digestive disorders than irregularity in filling the stomach. The activity of the digestive tract which is most likely to be disturbed by irregularity or a change in meal time is defecation. When the hours of light and darkness, meal times and the body temperature curve of the members of Linhard's crew in the arctic regions were reversed (Investigations into Conditions Governing the Temperature of the Body, Denmark, expedition Gronnøysk, number 1, Copenhagen, 1910) he observed that defecation was the physiologic activity most difficult to adapt to the new schedule.

#### MASTURBATION IN A GIRL OF 6 YEARS OF AGE

*To the Editor*—What is the routine therapy for masturbation in a female child? The patient is a white child aged 6 who had been perfectly normal until two months ago, when her mother noticed that she was practicing masturbation. Both physically and mentally the child is normal for her age. There are no other abnormal traits. I would not consider an occasional act alarming, however, this child's habits are particularly insistent and the mother is exceedingly worried. I would appreciate advice as to the best method to cope with this situation.

M. D., Texas

*ANSWER*—The first step should be the elimination of any local causes such as tight clothing, pinworms, eczema of the labia and vulvovaginitis. Corrections of such factors will frequently be followed by disappearance of the habit. In the absence of any of these findings it is more important to assure the parents that there is no evidence that the habit will do the child any physical harm. The harm lies in the worry and guilt that develop in the child following threats of imbecility, insanity and actual physical punishment by the parents. The child should be assured that it is a normal phenomenon and encouraged in the belief that it is of a transitory nature if anything is said at all. It is even better to ignore the act. In general, long periods of lying in bed before going to sleep or awakening should be avoided, also sleeping in very warm soft beds or under warm bedclothing. Cool morning baths have a beneficial effect. It is also well to study the child's life to see if any sudden changes or sources of dissatisfaction have occurred. Such adjustments may solve the problem.

#### TREATMENT OF THYROTOXICOSIS

*To the Editor*—Will you outline a course of medical treatment for toxic goiter? The patient is a married woman aged 30, with basal metabolism +10, blood pressure 130 systolic and 90 diastolic, weight 160 pounds (72.6 Kg) and height 5 feet 7 inches (170 cm). She had infected tonsils which have recently been removed and there is some improvement noted. All other physical findings are negative. Any suggestions will be welcomed. This goiter is of the toxic type and there should be no iodine deficiency, living as she does near the seacoast.

M. D., Maryland

*ANSWER*—If the patient is not taking iodine, a basal metabolism of plus 10 per cent should be considered within normal limits. The administration of iodine might mask any thyrotoxicosis present and reduce the level of basal metabolism to within normal limits. Before deciding on treatment, it is very important to know whether or not the patient is thyrotoxic. In rare instances, persons with metabolic rates of only plus 10 per cent are thyrotoxic.

For purposes of diagnosis, the following routine should be followed. Several determinations of the basal metabolism (at least three or four) should be taken on successive days at a time when the patient has not been receiving iodine for at

least two weeks. Iodine should then be administered and another series of metabolism tests run about two weeks after its administration is started.

If a significant reduction in metabolism occurs, as for example from plus 10 to minus 15 per cent, provided the metabolism readings are consistent and there is definite improvement in the clinical condition of the patient, it may be concluded that the patient is thyrotoxic. However, it should be borne in mind that there are many causes of nervousness besides thyrotoxicosis.

In some instances in which the disease is present in a mild form and the basal metabolism is only slightly elevated, it is possible to hold toxic goiter in check by the administration of iodine alone until the disease disappears. In general, however, it is unwise to carry out this form of therapy except in the clinics with a great deal of experience in the treatment of thyroid disease. The best treatment for toxic goiter in many instances is a subtotal thyroidectomy after adequate preparation.

#### EXCESSIVE GROWTH AND CONVULSIONS

*To the Editor*—Up to two years ago a youth aged 15 was squat and rotund. His height is now 6 feet (183 cm) and he weighs 135 pounds (61 Kg). He has gained in height more than 1 foot during this period. Two years ago he had a convulsive attack involving the flexor muscles of the fore extremities. He had no recurrence until one month ago, when he had three seizures, two within two hours. He loses consciousness during the seizure. He does not have nausea or bite his tongue during a seizure. He has premonition of an attack and had one attack when asleep. He takes great interest in athletics and exercises sometimes to excess. His behavior is normal. His eyes react to light and in accommodation, there is some injection of the efferent vessels but no excovertion or choking of the optic disks. He is much taller than any one of his relatives. The thought occurs to me that there is in this case a hyperactive pituitary gland. Blood pressure is 118 systolic and 79 diastolic.

M. D., Maryland

*ANSWER*—It would be impossible to attempt a diagnosis in this case or to make a guess at the cause of the convulsions without much more information. A growth of 12 inches in two years is abnormal. It would seem that there is a relationship of the convulsions to this growth. The patient's blood pressure must be determined in the lying, sitting and standing positions and in response to exercise. A sedimentation rate and a stereoscopic roentgenogram of the skull should be done in an effort to find a slow growing tumor such as a pinealoma. It is important to know whether there has been a normal development of the secondary sex characteristics. Hypogonadism would be more likely to produce this development than would hyperpituitarism. Roentgenograms of the wrists would indicate, by a determination of the bone age, whether the metabolism and maturation were probably within normal limits. The roentgenograms would also show whether the epiphyses were closing and if much more growth might be anticipated. An electroencephalogram would indicate with reasonable certainty whether or not epilepsy is to be considered as a cause of the convulsions. If no abnormalities are detected on any of the examinations, it is quite probable that there was an abnormal growth stimulus due to a temporary endocrine imbalance and no particular treatment would be indicated.

#### EFFECT OF TYING OFF ONE URETER

*To the Editor*—What would be the physiologic and pathologic effect of tying off one of the ureters? What is the cure for a ureterovaginal fistula? This occurred after the repair of a cystocele.

M. D., New York

*ANSWER*—When a ureter is isolated and tied off there is usually hydronephrosis followed by atrophy of the kidney. The other kidney, provided it is healthy, undergoes compensatory hypertrophy and carries on satisfactorily.

If the ureter has been injured during a pelvic operation, leakage of urine is usually not apparent at first and it may not occur until a week or ten days after operation.

In the case in question an attempt to pass a ureteral catheter would scarcely be worth while. The patient should be managed expectantly, for patients with postoperative ureteral leakage of urine tend to progress to spontaneous cure as the result of a gradual development of ureteral occlusion. In experimental animals the flow of urine is practically always sufficient to prevent spontaneous closure of the injured ureter. In humans the results are not so ideal, but watchful management frequently suffices.

In the event of failure of expectant care the choice of procedure lies between removal of the affected kidney and transplantation of the ureter. Nephrectomy is definitely preferable to transplantation of the ureter into the bowel and is preferable to attempted transplantation into the bladder.

## NERVOUS AND MENTAL EFFECTS OF THE SULFONAMIDES

SAM C. LITTLE, MD

ANN ARBOR, MICH

Sulfanilamide was first synthesized in 1908 by Gelmo. From that time until 1932 when Domagk demonstrated that azosulfamide (prontosil) could protect mice against streptococci the drug was relegated to a relatively unimportant niche among the 700 dyes. After Domagk reported his results in 1935 however this new antibacterial agent became generally known, and since then the story of sulfanilamide and the other sulfonamide derivatives has become common knowledge.

At one time or another, one of the sulfonamide derivatives has probably been exhibited in every illness known to man. Newer and more effective derivatives are constantly being brought out and disease after disease falls before the progress of the new chemotherapy. As with other dramatic new treatments however, the toxic effects of these drugs are being neglected among a welter of favorable reports. The effects of this group of drugs on the nervous system has hardly been investigated, yet the nervous system is frequently injured.

Earlier theories of the mode of action of sulfanilamide suggested that it stimulated the defense forces of the body, so that phagocytosis of pathogens was increased. This theory has been discarded, and it is now generally agreed that the drugs are primarily bacteriostatic. These compounds in some way interfere with the rate of growth of bacterial cells, possibly through disturbance of the enzyme system within the cell. The discarded theory had to assume that the toxic effects of the drugs were side effects unrelated to the beneficial action, but it is not unlikely that many of the toxic effects are an integral part of the effect of the drugs on cells, whether bacterial or human. It is possible that the synthesis of new multipotent derivatives will be brought to a standstill by the disappointing discovery that the more toxic these drugs are to bacteria the more toxic they are to the human cell.

The kidneys serve as the major excretory channel for the absorbed drugs. Great caution should be used when one prescribes the sulfonamide drugs for patients with impaired renal function. When toxic manifestations do arise, increasing the fluid intake will expedite the elimination of the drug from the body.

It is now fairly well established that the toxic symptoms of nausea, vomiting and diarrhea, which so often

accompany the administration of sulfonamides, originate in the central nervous system. Headaches, tinnitus and dizziness occur frequently in persons receiving any one of the sulfonamides. It does not follow, however, that the magnitude of these reactions is an accurate indication of the seriousness of the toxic effects of the drugs on the nervous system. It will be seen that some of the least nauseating drugs produce the most damage to the nervous system.

It is convenient to consider the drugs individually, with the neurotoxic effects of each.

### AZOSULFAMIDE (NEOPRONTOSIL)

Azosulfamide was used only a short time and was then supplanted by sulfanilamide. Cornwall<sup>1</sup> reported a case of mild dysmorphismia, with auditory and visual hallucinations, following the use of azosulfamide.

### SULFANILAMIDE

After applying solid sulfanilamide directly to the arachnoid of rabbits' brains, and after also injecting it into the cortex, Russell and Falconer<sup>2</sup> concluded that the slight damage seen was a foreign body reaction to the particulate substance and not in any way specific to the drug.

There are quite a few reports concerned with the toxicity of sulfanilamide for the nervous system of animals. Long and Bliss<sup>3</sup> noted that after prolonged administration of sulfanilamide to mice spastic paralysis and symptoms of vestibular dysfunction developed. Hawking<sup>4</sup> gave intraperitoneal injections of sulfanilamide to 10 rabbits. In all these animals extensor spasms developed from which 7 recovered completely and 3 died. The animals that died showed damage to the anterior horn cells and to some midbrain cells. Rosenthal<sup>5</sup> and Nelson<sup>6</sup> found that repeated doses of sulfanilamide to rabbits and hens caused symptoms suggestive of a peripheral neuritis (somewhat similar to triorthocresyl phosphate neuritis). Their histologic studies showed mild peripheral neuritis in 20 per cent of the rabbits and 33 per cent of the hens. Eighteen per cent of the hens also showed slight damage to the spinal cord. Bieter and his associates<sup>7</sup> gave hens large

doses of sulfanilamide, sulfapyridine, sulfathiazole, sulfamethylthiazole, sulfanilyl di-methyl-sulfanilamide and sulfaphenylthiazole for two weeks. Sulfanilamide caused the mildest injury to the nervous system of any of the sulfonamides used in this experiment. The damage was limited in the case of sulfanilamide to very mild changes in the peripheral nerves in 66 per cent of the animals and to a slight change in the posterolateral myelin sheaths of the spinal cord in 16 per cent.

As sulfanilamide has been used longer than any of the other members of the group now in general use, it is not surprising that many more reports of its clinical toxicity are available.

A mild depression or euphoria occurring during the use of this drug is common. A more localized cerebral effect may cause peculiar syndromes such as the case of severe dysmorphism (without other mental changes) reported by Weitzen.<sup>8</sup> In this case there were angular and curvilinear distortions, so that objects looked like the images seen in the "trick" mirrors of side shows. Distance perception was disturbed, and telopsia and micropsia occurred. The dysmorphism disappeared two days after the drug was withdrawn. Higgins<sup>9</sup> reported a case in which aphasia, agraphia and stammering appeared three times, each time on the third day of sulfanilamide medication. The patient was otherwise normal mentally during the medication, and the syndrome disappeared quickly after the drug was withdrawn.

When cortical depression progresses further, frank psychoses occur as a result of sulfanilamide therapy. A review of the literature reveals that 13 cases of psychoses following sulfanilamide therapy have been reported.<sup>10</sup> It is probably true that many more abnormal mental reactions have occurred than have been reported, because frequently this reaction is taken as a matter of course. In these 13 cases the drug had been administered for periods varying from fifteen minutes to forty days. In 2 cases the reaction appeared on the first day. Most of the psychoses appeared from three to ten days after drug therapy had been started, but in 2 cases the psychosis appeared after the drug had been discontinued, in 1 fourteen days later and in the other four days later. Several of the patients had had sulfanilamide before or had been given an interrupted course of the drug. It is interesting to speculate whether this intermittent administration might not have caused a sensitization to the drug somewhat like that seen in the use of protein materials. The average daily dose ranged from 3 to 8 Gm, with most of the patients receiving an average daily dose of about 4 Gm. One patient<sup>11</sup> would become so irrational, confused and excited ten to fifteen minutes after receiving a single dose of the drug that restraints were necessary. This train of events occurred three different times. Usually the picture in

sulfanilamide psychoses is that of an ordinary toxic psychosis with confusion, disorientation, depression or euphoria, auditory and visual hallucinosis and distractibility. Paranoid trends are not infrequent. As in other toxic psychoses, the particular manifestations probably depend somewhat on the prepsychotic personality of the patient. The psychosis usually clears up promptly following the discontinuance of the drug. Residual changes were not noted in most of the cases reported, but 1 patient<sup>12</sup> died. In this instance the toxic symptomatology appeared two weeks after the drug had been stopped.

Case 1 illustrates the usual type of toxic psychosis seen after the administration of sulfanilamide.

CASE 1—H. E., a man aged 58, a professor, had a partial gastric resection for peptic ulcer on Nov 15, 1938. On November 22 a septic type of fever developed and his urine was found to be severely infected. He was given 5 cc of 25 per cent of azosulfamide (neoprontosil) intramuscularly at 6:45 p.m. on November 26. No particular mental abnormality was noted. Between 4 and 8 p.m. of the next day (November 27) he was given, by intravenous administration, 5 Gm of sulfanilamide dissolved in 5 per cent dextrose. At 10 o'clock the nurses reported that he was "talking at random and could not talk coherently." He had to be observed continuously, and sedation with paraldehyde was necessary. The following day he was irrational and was talking nonsense such as "I am an equation, you're the denominator, that's the numerator." He appeared apprehensive and was disoriented. On the afternoon of November 28 he was clear enough to answer questions by nodding his head, but he would speak when urged, answering questions with "yes" and "no." The next morning he was drowsy and wanted to know where he was, but that afternoon, although there was a slight dysarthria, his mind was entirely clear. From that time on no mental abnormality was noted. In this case attention should be called to the fact that only one dose of sulfanilamide was given intravenously and that the patient's psychosis appeared six hours after the drug was started. It is entirely possible that the small dose of 120 sulfamide sensitized him to the later dose of sulfanilamide. The psychosis had entirely cleared up within thirty-six hours after the drug had been stopped.

The next report is that of a case of schizophrenia which appeared to have been precipitated by sulfanilamide.

CASE 2—G. B., a white schoolgirl aged 21, was admitted to the Neuropsychiatric Institute on Dec 15, 1941. She was the oldest of three children and had been somewhat spoiled. The family history was not remarkable. For three days following birth she had been anuric, and since then there had been frequent diurnal and nocturnal enuresis. She had talked in her sleep, had masturbated frequently and had expressed a wish to be a man like her father. Her interest in church work was such that at a Bible camp she had "consecrated her life as a Christian worker." Her friends described her as conscientious, cheerful, sweet and well liked. The enuresis appeared in the winter of 1940 but returned in the spring of 1941. Shortly before she left for Chicago to attend a college institute, Sept 3, 1941, she started taking alternating courses of sulfanilamide and methenamine. From September 1 to about September 7 she took 0.6 Gm of sulfanilamide four times daily (taking 0.3 Gm of sodium bicarbonate with each dose). Then for about two weeks she left off the sulfanilamide (taking 0.3 Gm of ammonium chloride four times a day) and took 0.6 Gm of methenamine four times a day. After a two-week course of sulfanilamide (and sodium bicarbonate) she

next and was followed by another two weeks course of methenamine and ammonium chloride. On about October 19 she again started sulfanilamide (and sodium bicarbonate) and continued this until October 22 when abnormal mental symptoms developed. On October 22 she became enuretic in class, was very much embarrassed and left precipitously. She told her homemaker that she had been masturbating that she felt dead all over and that all her female organs were rotting away. She felt dead and frozen, sinful and hopeless and said that the Bible condemned her. She kept tapping her head 'to see whether it was dead or alive' and she constantly picked at her hands and arms. On admission to the Neuropsychiatric Institute physical examination was essentially negative except that a smooth liver was felt on deep inspiration. A neurologic examination was negative. There were no indications suggestive of a peripheral neuritis. The urologic consultant felt that the patient probably had an uninhibited neurogenic bladder. The test for blood sulfanilamide was negative. The hematology was normal and urinalysis bromsulphalein liver function tests spinal fluid examinations and skull roentgenograms were negative. She complained of confusion and difficulty in thinking and said that her head felt tired and her chest and abdomen empty. She was quiet, withdrawn and did not appear to have hallucinations. Orientation and memory were good. A psychometric examination revealed an intelligence quotient of 103, but the psychometrist expressed the opinion that her intelligence had originally been around the 125-130 level. A Rorschach analysis was interpreted as indicating catatonic schizophrenia with strong depressive elements. While in the hospital she expressed many feelings of self accusation and futility. She continued to pick at her hands and arms and complained that her skin felt numb and that her body was dying. Her status was generally unimproved throughout her hospitalization. Electric shock therapy was recommended but her relatives did not agree to this and they removed the patient from the hospital, against advice, on Feb. 4, 1942.

In this case the administration of the sulfanilamide had been intermittent, and a rather typical schizophrenic reaction appeared shortly after she had started on her third course of the drug.

Peripheral neuritis is one of the more common complications of the nervous system after the use of members of the sulfonamide group of drugs. Sulfanilamide itself, however, produces neuritis less often than other derivatives. Waugh<sup>13</sup> reported on the frequency by saying that he had observed only 1 case of peripheral neuritis among 650 patients treated with sulfanilamide. In Waugh's case,<sup>13</sup> painless neuritis of the left anterior tibial nerve developed on the second day of the third course of sulfanilamide therapy for gonorrhea. Symptoms of neuritis had not been noted during the previous (longer) courses of sulfanilamide. The average daily dose was 4.4 Gm. The drug was withdrawn soon after the neuritis appeared, physical therapy was started, and in five or six weeks 30 per cent of function had returned. In Janet's case<sup>14</sup> the neuritis was of the arm and thorax and lasted three days. Ornstein and Furst<sup>15</sup> reported that weakness of adduction of the thighs, a waddling dystrophic gait and a patchy distal hypesthesia of the legs developed in 1 case one and a half months after a course of combined sulfanilamide and fever therapy. Garvey, Jones and Warren<sup>16</sup> however,

noted a similar syndrome occurring after the use of fever therapy whether sulfanilamide was used or not. They observed that the spinal fluid protein was elevated in these cases and compared the picture to the Guillain-Barré syndrome. It therefore seems probable that sulfanilamide had nothing to do with the occurrence of neuritic symptoms in the cases reported by Garvey and his associates and by Ornstein and Furst.

Fisher and Sidney<sup>17</sup> reported 2 cases of encephalomyelitis following the use of sulfanilamide. In their first case 1 Gm. of sulfanilamide was given daily for thirteen days. Two days after the drug was stopped symptoms of a transverse myelitis developed at the first lumbar segment. There was pleocytosis of the spinal fluid. The sensory level ascended to the second thoracic segment in two days and the patient died a respiratory death. Postmortem examination showed softening of the cord substance and vascular lesions of thrombosis, congestion and hemorrhage were prominent in the small vessels of the nervous system. The vessel walls showed fibrinoid necrosis and were surrounded by areas of demyelination. Since this patient had lupus erythematosus, it is not altogether certain that the transverse myelitis was due to the sulfanilamide. In their second case radicular pains, weakness and increased reflexes in the right lower extremity developed after sulfanilamide therapy. These symptoms persisted even after the drug had been discontinued. This patient had received 3 Gm. of sulfanilamide daily for six days before the symptoms developed. Norbury<sup>18</sup> reported a case of transverse myelitis developing in a patient receiving an average daily dose of 3.3 Gm. of sulfanilamide for eight days. Hematoporphyrinuria was present. Some recession of the syndrome occurred six days after the drug had been discontinued, and recovery was complete in six months.

Bucy<sup>19</sup> has reported a case in which a toxic optic neuritis developed three times after a single 0.3 Gm. tablet of sulfanilamide, and each time the symptoms would subside after the drug had been withdrawn. It is noteworthy that this patient had had two previous courses of sulfanilamide without the development of symptoms of optic neuritis.

Transitory myopia developing acutely in the course of sulfanilamide therapy has often been reported.<sup>20</sup> Vision usually returns to normal within forty-eight hours after the drug has been stopped. Most investigators agree that the symptom is due to a swelling of the lens, either as an allergic reaction to the drug or as a result of a difference between the osmotic tension of the lens and the aqueous (this difference being caused by unequal distribution of the drug within the eye).

#### SULFAPYRIDINE

Russell and Falconer<sup>2</sup> found that sulfapyridine in solid form produced irritation of the rabbit brain only as a foreign body, not in a specific manner. It was somewhat more irritant than sulfanilamide owing to its greater insolubility. Bieter and his associates<sup>7</sup> found

that chickens given sulfapyridine in high concentrations for two weeks showed more injury to the nervous system than those given sulfanilamide but less injury than those given any of the other sulfonamides tested. Of the chickens given sulfapyridine, 91 per cent showed patchy swelling or condensation of the myelin sheaths of the peripheral nerves, but the changes were mild in all except 3. In these 3 chickens, the myelin sheaths and axons had partially disappeared. One spinal cord showed a slight change in the posterior columns (sheath swelling), but all the brains were normal.

Johnstone and Forgacs<sup>21</sup> reported on the administration of sulfapyridine (the sodium salt given intramuscularly) to 5 children suffering from meningococcal meningitis. In these patients cerebral symptoms of confusion, restlessness and irritability persisted after the spinal fluid had become normal, and in some instances meningeal signs persisted. Rapid improvement occurred in these symptoms when sulfapyridine was discontinued. Those patients died who did not have the drug withdrawn. He stated that if meningeal and cerebral symptoms persist three days after sulfapyridine therapy is started, these symptoms are probably due to the drug.

Pluegge<sup>22</sup> refers to a case of sciatica due to sulfapyridine reported in the German literature and to 2 cases of encephalomyelitis reported in the American literature as being due to the same drug. Pluegge himself reported that a patient received sulfapyridine for seven days (average dose 3 Gm daily) and on the twenty-sixth day polyneuritis of the femoral, tibial and peroneal nerves developed. There were no sensory disturbances, but areflexia was noted in the involved area. Therapy did not help the neuritic symptoms. He also reported that another patient was suffering from meningococcal meningitis and was treated with sulfapyridine. Six weeks after the spinal fluid became normal weakness and ataxia appeared, and loss of tendon reflexes in the legs was noted, and two weeks later bladder symptoms developed. All neurologic complications were improving when the patient was seen three months later.

Something should be said about the dangers of intraspinal injections of the sulfonamides,<sup>23</sup> particularly sulfapyridine and its sodium salt. Injections of sodium sulfapyridine are caustic and have been known to cause necrosis of the spinal cord at the level of the injection.

#### SULFANILYL SULFANILAMIDE (DI-SULFANILAMIDE)

Sulfanilyl sulfanilamide, or di-sulfanilamide, fortunately was not released for general use in the United States. In Europe it was widely used under the name "disulon." At the present time it has fallen into disrepute principally because of the number of reports concerned with its toxicity for the nervous system. Rosenthal<sup>5</sup> and Nelson<sup>6</sup> in this country found that the drug produced less clinical evidence of weakness in rabbits than sulfanilamide, but microscopic studies revealed that lesions of the peripheral nerves were four times as frequent with di-sulfanilamide as with sulfanilamide.

Instances of peripheral neuritis due to this drug have been reported.<sup>24</sup> The clinical picture of this neuritis is fairly constant. From one to three weeks after a long or short course of sulfanilyl sulfanilamide pain suddenly appears in the calves, and sometimes in the arms. This pain frequently disappears in a few days, but a day or two after its onset, weakness of the hands and feet appears. This progresses until, in severe cases, there is a veritable distal quadriplegia, which is particularly pronounced in the extensor muscles. The adductor pollicis is almost always more affected than any other muscle, and a reaction of degeneration may sometimes be noted in the thenar muscles. Sensory changes are slight or absent. The deep tendon reflexes in the distal parts of the extremities are usually lost, but they may be hyperactive.<sup>25</sup> Recovery is slow but may become complete in from several weeks to nine months, depending on the severity of the process.

#### DI-METHYL DI-SULFANILAMIDE

In the studies of Bieter<sup>7</sup> comparing the toxicity of the various sulfonamides, di-methyl di-sulfanilamide was more toxic to the nervous system than sulfanilamide, sulfapyridine, sulfathiazole or sulfamethylthiazole. In the animals given di-methyl di-sulfanilamide, each peripheral nerve examined showed fragmentation and vacuolization of the myelin sheath and damage to the axons. Six of the 11 spinal cords examined showed extensive damage, 1 cord being completely destroyed transversely. Six of the brains showed vascular damage and swelling of the neurons.

This drug, like sulfanilyl sulfanilamide, was given a short clinical trial in the United States, and its deleterious effects were so great that it was never distributed generally. In Europe, however, it found some general use until it was observed that many cases of peripheral neuritis followed its use. Bannick, Brown and Foster<sup>26</sup> used this drug in 32 cases, and peripheral neuritis occurred in 2. In each of these only the lower extremities were involved. The neuritis from this drug seems to disappear more rapidly than it does with sulfanilyl sulfanilamide. In 1 case, however, recovery was not complete in sixty days. Most of the cases of polyneuritis due to this drug<sup>27</sup> are reported in the

European literature in which the drug was used under the names "uliron," "disceptal," and "D 373."

Two cases of fatal myelomalacia due to the use of di-methyl di-sulfanilamide have been reported.<sup>28</sup>

#### SULFATHIAZOLE

Bieter's work<sup>29</sup> showed that sulfathiazole was intermediate in nervous toxicity between sulapyridine and di-methyl di-sulfanilamide. There was some injury to all the peripheral nerves of the chickens examined but in only 3 was the damage advanced. Microscopic studies revealed that 6 of the 11 spinal cords had swelling of the myelin sheaths and axons and some cords showed demyelination and fragmentation of all the neural elements. In 4 of the brains mild demyelination and changes in the endothelium of the vessels were present. Bieter and his associates also reported 2 cases of peripheral neuritis due to sulfathiazole. Their first patient had received sulfathiazole steadily for five and one-half months. Seven weeks after sulfathiazole had been started nerve deafness appeared in the left ear. A few days later peroneal weakness and foot drop appeared on the right. When the drug was withdrawn some motor improvement was noticeable in two weeks. Their second patient had received 27 Gm of sulfathiazole in five and a half days when the drug was stopped because numbness and tingling in the hands appeared. The symptoms quickly disappeared after the drug was stopped.

Weinberg and Knoll<sup>29</sup> noted a syndrome occurring in the course of sulfathiazole therapy which they thought resembled amyotrophic lateral sclerosis. It appears, however, that the syndrome they described is quite different from amyotrophic lateral sclerosis and resembles more a mild peripheral neuritis. The patient complained of cramps in the arms and hands and of tremors and clumsiness of the hands. Fibrillations were noted in the thenar muscles and in the forearm muscles. The symptoms would promptly disappear when medication was withdrawn and recur when the drug was started again. The last time the drug was used they gave vitamin E concurrently with the sulfathiazole, and as the syndrome did not appear they felt that vitamin E had prevented the recurrence of the syndrome. Bloom, Leech and Shaw<sup>30</sup> reported a case of temporary blindness due to sulfathiazole. The ophthalmoscopic examination showed tortuosity and dilatation of the retinal vessels, and small petechial hemorrhages and crystal-like spots were present around the macula. After the drug was stopped vision returned to normal in about ten days.

The following cases illustrate the toxicity of sulfathiazole for the nervous system.

CASE 3—M. A., a white woman aged 64, was admitted to the University Hospital in coma on Nov. 11, 1941. While the patient was recovering from minor injuries sustained in an automobile accident on September 14, pleuritic pain developed for which she was given sulfathiazole. From October 10 to 16

she received 36 Gm of sulfathiazole. Then the drug was discontinued for two days because of nausea and vomiting, but on October 18 it was started again and by October 29 she had received a grand total of 69 Gm. Sulfathiazole was not given after October 29. On November 5 a sore throat developed. On November 6 she took a single 0.2 Gm tablet of sodium propyl-methylcarbinyl allylbarbiturate (seconal), became stuporous and remained so until admission to the University Hospital. Her relatives said that for three or four years she had had severe tremor of the extremities particularly on intention. On admission the rectal temperature was 106 F, the pulse rate 140, the respiratory rate 44 (Cheyne-Stokes type) and the blood pressure 98 systolic and 58 diastolic. Hematologic studies showed 85 per cent hemoglobin, 4,400,000 erythrocytes and only 1,200 leukocytes of which 2 per cent were neutrophils, 97 per cent lymphocytes and 1 per cent monocytes. There were dirty gray ulcers on the hard palate and in the right nostril. The patient was semicomatose but would nod her head in answer to questions, or would even speak a few words when urged. A neurologic examination soon after admission showed sensation to be intact as far as could be determined. The corneal reflexes were absent and there was an exposure keratitis. The pupils were irregular and the right was slightly larger than the left. There was a minimal central paresis of the right side of the face and the tongue and jaw deviated to the right. There was a paresis of the right extremities with some spasticity. The deep tendon reflexes were increased on the right and absent on the left. Mayer's sign was absent on the right and present on the left. Hoffmann's sign was more distinct on the right and definite Chaddock and Oppenheim signs were obtained on the right. Jacksonian convulsive movements were present in the right lower extremity from time to time. Roentgenograms of the skull and an examination of the spinal fluid were negative. The patient was treated with blood transfusions, pentose nucleotide and liver extract and by November 10 the leukocyte count had risen to 9,000. The following day she conversed with nurses and relatives but was still a little confused. A neurologic examination on December 3 disclosed some inattention to the right side of the body, and possibly some slight confusion of laterality but no other signs of aphasia. She was perfectly oriented but was definitely facetious and could not repeat more than four digits forward. The pupils were now equal though irregular. There was slight drooping of the right corner of the mouth but no definite facial paresis. There was mild generalized paresis of the right extremities with slight increase in tone on the right. The deep tendon reflexes were more active on the right but no pathologic pyramidal signs were present. Gross intermittent tremors (somewhat like those of paralysis agitans) were present in the hands. The patient continued to improve after this date, and at the time of discharge on Dec. 24, 1941 she was in good general physical and mental condition except for an evident paralysis agitans syndrome with tremor, loss of associated movements and masking of the tacies.

This case illustrates the toxic effect that sulfathiazole may have on a previously diseased nervous system.

Case 4 is another illustration of the toxicity that sulfathiazole has for the nervous system.

CASE 4—F. W. M., a white man aged 60, was admitted to the University Hospital on Dec. 24, 1941. On November 15 he had had right-sided pleuritic pain with fever, and he received a course of sulfathiazole, the exact duration and amount of which is unknown. When he was admitted to the University Hospital he was complaining of dyspnea and general malaise and a diagnosis of empyema was subsequently made. The admission blood count showed 60 per cent hemoglobin, 3,630,000 erythrocytes and 1,150 leukocytes. The whole stained smear contained only 37 leukocytes of which 35 were lymphocytes and 2 were monocytes. A neurologic examination on the day of admission showed vibratory appreciation to be lost bilaterally.

as high up as the iliac crests. There were numerous patches of chorioretinitis in both fundi, the left corneal reflex was less active than the right, there was a definite paresis of the lower portion of the left side of the face, and there was slight tremor of the tongue. The patient had had a conduction deafness in the left ear for many years. Owing to debilitation, tremulousness was apparent in all movements of the extremities. The right triceps was absent, but otherwise the upper deep tendon reflexes were normal. There was a suggestion of atrophy in the first interosseous space bilaterally. The patellar reflexes were hyperactive and equal and the achilles reflexes absent bilaterally. There was a slight Chaddock sign on the right and a definite Babinski sign was elicited on the left. There were no definite motor abnormalities. The patient was given pentose nucleotide and blood transfusions, and the leukocyte count rose rapidly, until on December 28 it was 5,000 and on December 29 it was 28,000. Immediately after this rise the blood count returned to normal. His empyema was drained successfully and he was discharged Jan 20, 1942 in excellent general condition. When he returned for a check-up on February 21, another neurologic examination showed that there were healing patches of exudate in the fundi and that there was still a very mild paresis of the lower part of the left side of the face. There was a coarse tremor of the tongue and of the outstretched hands. There was slight ataxia on the finger to nose test. The left lower extremity showed slight spasticity, vibratory sensation was reduced at the right ankle and lost at the left, the ankle jerks were hyperactive but equal, and there was a suggestion of a Babinski sign on the left. The examination was otherwise normal.

In this case, it is true, there is a possibility that the central nervous signs might have been due to emboli (the retinal findings were suggestive of emboli), but there were no other clinical evidences of embolic phenomena. In both case 3 and case 4, neutropenia was well defined, and the question may arise as to whether the nervous and mental symptoms might not have been due to the neutropenia rather than to the direct toxic effect of the drug on the nervous system. The papers of Hunter,<sup>31</sup> Reznikoff<sup>32</sup> and Kracke,<sup>33</sup> which are concerned with the syndrome of granulocytopenia alone, make no mention of nervous or mental complications of this disease.

Case 5 illustrates the abnormal mental reactions and psychoses sometimes seen during the use of sulfathiazole.

CASE 5—H V, a white man aged 57, cut his face while shaving on Jan 7, 1942. On Jan 10 cellulitis of the right side of the face developed and on admission to the University Hospital on January 13 there was intense inflammation of the right side of the face. The temperature was 103.8 F, the pulse rate 120 and the respiratory rate 25. He showed evidence of general toxemia with mild confusion and slight lowering of the level of consciousness. Diabetes mellitus was discovered soon after admission, and when the patient was told of this illness on the third hospital day he became mildly depressed. During the first five days of his stay in the hospital he received 6 Gm of sulfathiazole daily. In addition, on the fifth hospital day prior to incision and drainage of the cellulitis he received an additional dose of 2 Gm of sulfathiazole. Several hours after the operation he became quarrelsome, resistive, aggressive, profane and generally uncooperative. He refused to remain in bed, insisted on walking to the bathroom and, when urinals were brought into his room, would throw them

down the hall toward the nurses' desk. In spite of this he seemed oriented and would take medication when it was brought to him. The next day (January 18, or the sixth hospital day) he was definitely facetious but was perfectly oriented and not so aggressive. There was some blunting of superficial sensation in the peripheral parts of the extremities, and vibratory sensation was slightly reduced at the left ankle. There was slight weakness of adduction and abduction of the fingers of both hands, and also of dorsiflexion of both feet. The biceps, triceps, radial-periosteal, patellar and achilles were absent bilaterally. A diagnosis of sulfathiazole intoxication was made, sulfathiazole was withdrawn and sulfadiazine substituted in doses of 6 Gm daily. From this time on he was also given 20 mg of thiamine hydrochloride, 20 mg of nicotinic acid amide and 0.1 Gm of ascorbic acid, each four times a day. Within thirty-six hours after the sulfathiazole had been withdrawn all mental abnormalities disappeared. Although the patient could not remember the exact details, he knew that his behavior had been objectional and apologized for this profusely. From this time on he was cheerful and cooperative. Examination on the seventeenth hospital day revealed that all the deep tendon reflexes had returned, and sensation and strength in the hands and feet were normal. Glycosuria practically disappeared after the sixth hospital day, and the diabetes was completely controlled when he was discharged in excellent general condition on the forty-ninth day.

It seems likely that the abnormal mental reactions of this patient after the operation were due mainly to the sudden increase in the blood sulfathiazole level resulting from the extra dose of 2 Gm of sulfathiazole. The signs suggestive of peripheral neuritis may have been due to the sulfathiazole, or they may have been associated with the diabetes. The toxic effect seemed to be specific for sulfathiazole in this patient, as all symptoms subsided after sulfadiazine was substituted.

#### SULFAMETHYLTHIAZOLE

Bieter's studies<sup>7</sup> showed that sulfamethylthiazole was only slightly more toxic to the nervous system of chickens than sulfathiazole, the changes being a little more advanced with the former drug. Brown and Herrell<sup>34</sup> treated 106 patients with sulfamethylthiazole, and in 3 patients they noted a "lower motor neuron" disturbance manifested by foot drop, which appeared one to two weeks after the drug had been stopped. Pain in the calves immediately preceded the foot drop. One patient also had weakness of the thumb and forefinger bilaterally. Only 1 of their patients had an interrupted course of sulfamethylthiazole therapy. Applebaum<sup>35</sup> observed a case of peripheral neuritis which came on six days after withdrawal of sulfamethylthiazole. In this case, bilateral weakness of the adductor pollicis was the first symptom, but it was soon followed by bilateral pain in the calves and bilateral foot drop. The drug was continued, regardless of the neuritis, and eventually a very distinct distal quadriplegia developed. At that time there were sensory changes in the extremities. The patient had had other sulfonamides before. Garvin<sup>36</sup> reported that a patient had tenderness and hyperesthesia of the legs on the seventeenth day of sulfamethylthiazole therapy and then, two days after the drug was stopped, became disoriented, had several generalized convulsions

and died. The postmortem examination of the brain revealed no abnormality. Another case of toxic psychosis with convulsions following sulfamethylthiazole therapy is reported by Roseman and Aring.<sup>37</sup> This psychosis appeared on the fifth day of a course of intensive sulfamethylthiazole therapy and it terminated in death. There were petechial hemorrhages scattered throughout the gray matter, but the white matter was entirely spared, contrary to the usual findings in toxic hemorrhagic encephalopathy. The predominant lesion was the drupedetic hemorrhage. Some perivascular necrosis was present. The blood vessel changes were mostly endothelial. In this case there were the following complicating factors: (1) The tissues contained abnormal amounts of lead (patient had worked in a lead factory for many years but had never had any symptoms of lead poisoning), (2) The patient was alcoholic. Perhaps this case is an illustration of the deleterious effect of sulfamethylthiazole in the presence of preexisting central nervous system disease.

In case 6 peripheral neuritis developed after a course of sulfamethylthiazole therapy.

CASE 6—A R., a white woman aged 47, was admitted to the University Hospital on March 7, 1940. Ten weeks before admission cellulitis of the right side of the face developed. Later severe headache appeared. On admission physical examination showed slight blurring of the margins of the optic disks and a small retinal hemorrhage in the right eye. The blood count revealed leukocytosis and some hypochromic anemia. Two blood cultures showed *Staphylococcus aureus* and a diagnosis of staphylococcal septicemia was made. A neurologic examination on the fifth hospital day was negative except for a questionable mild sixth nerve paresis on the right and a subsiding papillitis. On the evening of the seventh hospital day the patient was given 4 Gm. of sulfamethylthiazole and thereafter for twelve days received 15 Gm. every four hours. There was moderate nausea and vomiting. After the drug was withdrawn, she continued to improve. A blood culture on the fourteenth hospital day showed no growth, and she was discharged on the thirty-third hospital day. Two days after discharge (sixteen days after sulfamethylthiazole had been discontinued), she noted sudden severe pain in both legs, some swelling of the dorsums of the feet and sudden foot drop, first on the right and then on the left. The pain in the legs improved gradually. One week later she vomited, lost consciousness and entered a local hospital for four days, but on discharge the foot drop was unimproved. One month after her previous discharge she was readmitted to the University Hospital complaining of pain above and behind the right eye. Examination showed that the previously diagnosed papillitis had subsided. There was also an area of localized cellulitis on the right wrist, but it was felt that it probably bore no relation to her previous illness. Neurologic examination disclosed a coarse tremor of the tongue, some atrophy of the small muscles of the hands (especially on the right), some weakness of the grip bilaterally and general weakness of the muscles about the hips, knees and ankles. There was almost complete loss of extension of the feet bilaterally, this being less noticeable on the right. There was mild weakness of the flexors of the feet. The upper tendon reflexes and the patellars were active and equal but the achilles were absent bilaterally. There were no pathologic toe signs. The nerve trunks in both lower extremities were tender, and there was a patchy hypesthesia of both lower extremities, this change being most noticeable in the fifth lumbar and first sacral segments. Vibratory sensation was slightly impaired at the right ankle. Casts were made to prevent talipes equinus deformity, and the patient was discharged. She returned to the University Hospital one

month later. In the interval she had taken 15 mg. of thiamine hydrochloride daily. There was no pain in the legs, but she had begun to notice some awkwardness in the use of her hands. There was hypesthesia over the second, third and fourth lumbar segments on the right, severe bilateral foot drop (worse on the left) was present, and the achilles reflexes were absent. Straight leg raising caused some pain on both sides, and there was slight pain on flexion of the neck. There was slight weakness of the grip, and mild atrophy was present in the first interosseous space bilaterally. The patient was seen again two months later, at which time there was some improvement in the foot drop so that she could extend her toes and feet slightly when she was lying down. The numbness in the lower extremities annoyed her considerably, and examination disclosed hypesthesia and hypalgesia below the midthigh region on the right and below the knee on the left. Motion and position sense was absent in the feet. The knee jerks were moderately exaggerated, and the achilles reflexes were hyperactive and equal but there were no pathologic toe signs. Four attempts to do a lumbar puncture were unsuccessful owing to the fact that the patient experienced extreme pain immediately after the needle passed through the dura, and it was felt that the needle was impinging on nerve trunks. Roentgenograms of the spine were negative. In spite of large quantities of thiamine hydrochloride, brewers' yeast and physical therapy, the patient showed little improvement during her stay in the hospital. She was not seen again after discharge.

In this case it is interesting to speculate as to the exact location of the lesion causing the foot drop and the sensory change. The achilles tendon reflexes were absent for a long time and then finally became hyperactive. The explanation for this is obscure, but it is possible that the peripheral neuritis subsided and unmasked symptoms due to involvement of the spinal cord itself.

#### SULFAGUANIDINE

As yet there is little evidence that sulfaguanidine is toxic to the nervous system. Perhaps this is because only relatively small amounts enter the blood stream.

#### SULFAPHENYLTHIAZOLE

Sulfaphenylthiazole is not used clinically. Bieter<sup>7</sup> found that it produces more injury to the nervous system than any of the other sulfonamides.

#### SULFADIAZINE

Sulfadiazine has only recently been introduced. It seems to have a wider range of therapeutic effectiveness than many of the others, perhaps owing to the fact that not so much of it is acetylated in the blood. With regard to its toxicity for the nervous system, Finland<sup>38</sup> treated 466 patients with this drug, and serious neurologic or psychiatric syndromes did not develop in any of his cases. Nausea and vomiting occurred in 92 per cent, and headache and dizziness were present in only 2 cases.

Recently a case of peripheral neuritis following sulfadiazine was observed, and it will be reported briefly.

CASE 7—W. H. M., a white man aged 70, was admitted to the University Hospital complaining of nausea and vomiting. Subsequent studies showed that these complaints were due to uremia and acidosis secondary to benign prostatic hypertrophy with urinary obstruction. On admission the patient was quiet oriented and cooperative. Physical examination was negative except for peripheral arteriosclerosis and pulmonary emphysema. Blood nonprotein nitrogen was 127 mg. per hundred

37 Roseman E. and Aring C. D. Encephalopathy Associated with Sulfamethylthiazole Therapy. *New England J. Med.* 224: 416-420 (March 6) 1941.

38 Finland, Maxwell, Strauss, Elias and Peterson. O. L. Sulfadiazine. *J. A. M. A.* 116: 2641-2647 (June 14) 1941.

cubic centimeters and carbon dioxide combining power 31 volumes per cent. The urine was mildly infected, and he was given 3 Gm of sulfadiazine daily from November 18 to December 7. He also received sodium lactate by mouth, and fluids were given in copious amounts. From November 26 to 29 an episode of confusion and hallucinosis occurred. During this time blood nonprotein nitrogen was 76.5 mg per hundred cubic centimeters and carbon dioxide combining power 99 volumes per cent. It seems probable that alkalosis was at least partially responsible for this episode. From December 8 to 12 he received 15 Gm of sulfadiazine daily. On December 10 a transurethral resection of the prostate was performed, and shortly after the operation the patient contracted bronchopneumonia. Sulfadiazine was increased to 4 Gm daily and continued at this level until December 18. On the latter date the patient was having elevations of temperature without leukocytosis, and it was felt that the fever was probably due to the drug, so sulfadiazine was discontinued. The pneumonia had completely resolved by December 18, but postoperative hemorrhage had occurred and several blood transfusions were necessary to combat a severe hypochromic anemia. On December 18 and 19 he was again having hallucinations and was confused and disoriented. On December 20 a hemostasis was done, and his mental status improved gradually thereafter. On December 22 he had recovered enough to talk coherently, and on that day he first began to complain of numbness of the hands and feet. There was a hypalgesia in the ulnar distribution on the left, and also profound weakness of the grip was present on the same side. The numbness of the left hand persisted after he had been discharged on December 18, but the numbness of the right hand and of the feet subsided rapidly. He returned on March 17 for a check-up, and it was at that time that the first complete neurologic examination was done. His mental state was normal. He did not remember ever having had any pain associated with the numbness in the extremities. Vibratory appreciation was absent at the ankles and present at the wrists. There was hypesthesia and hyperalgesia in the distribution of the left ulnar nerve. The grip was moderately weak on the left, and there was severe paresis of the left adductor pollicis. Some atrophy was present in the first left interosseous space. There were no other sensory or motor abnormalities. The biceps, triceps, radial-periosteal, patellar and achilles reflexes were moderately active and equal.

#### COMMENT AND SUMMARY

Animal experiments seem to indicate that all members of the sulfonamide group have a toxic effect on the nervous system, the parent substance, sulfanilamide, being the least toxic, and some of the newer derivatives being the most toxic. The toxic effects are probably an integral part of the primary effect of the drugs on all cells, bacterial or human. It has been suggested<sup>39</sup> that some of the deleterious nervous and mental effects may be dependent on cerebral anoxia resulting from hemoglobin, attaching itself more readily to the sulfonamide group than to oxygen. Intermittent administration of a single sulfonamide or successive administration of different sulfonamides seems to predispose to the development of toxic nervous system symptoms, possibly through a sensitization process. A review of the clinical reports, in general, confirms the results of the animal experiments. The drugs appear more neurotoxic in the presence of preexisting disease of the nervous system. The following abnormal conditions have been reported as due to the use of the sulfonamides: dysmorphism, aphasia, agraphia, stammering, toxic psychosis, peripheral neuritis, encephalomyelitis, myelitis, optic neuritis, transitory myopia, meningeal signs, blindness and convulsions.

## SERIOUS COMPLICATIONS OF RUPTURED INTERVERTEBRAL DISKS

WALTER E. DANDY, MD  
BALTIMORE

Ruptured intervertebral disks are now known to be exceedingly common, they are, in fact, among the most frequent lesions treated surgically. Over 95 per cent of them are in the lumbar region, where they explain the overwhelming percentage of recurring pains low in the back plus sciatica in one or both legs. With rare exceptions it is now possible to diagnose and localize those in the lumbar region without spinal injections of iodized oil, air or other contrast medium or even without a lumbar puncture.<sup>1</sup> Up to the present time the course in all reported cases of ruptured disk except our first 2 has run true to form and there were no serious complications. Three serious sequelae encountered during the past month emphasize the potential dangers of this simple lesion when the diagnosis and treatment are delayed. One of the disks ruptured was in the cervical, another in the thoracic and the third in the lumbar region. The rupture of the cervical and the thoracic disk had disastrous results—total paralysis and death from pressure necrosis of the spinal cord in the former, in the latter the paralysis has partly cleared. The rupture of the lumbar disk caused permanent sensory paralysis in addition to long-continued pain and loss of bladder function with subsequent infection of the urinary system.

In addition to these 3 recent cases I have had 2 cases of ruptured disk (lumbar disk) with complete paraplegia (previously reported) and loss of bladder function and another (lumbar disk) with long-continued bladder incontinence and infection. These 6 cases of serious complications occurred in a series of perhaps 300 operative cases of ruptured disk, a percentage, therefore, of about 2. All the sequelae could have been prevented with early diagnosis and treatment. Although all the patients except the one with a cervical disk ruptured have survived, the paralysis of the patient with a thoracic disk ruptured will probably be permanent and perhaps some permanent stigmas will affect the others, particularly those with infection of the urinary tract. Delay in treating a ruptured cervical or thoracic disk is disastrous because only a few hours is required to destroy the spinal cord irreparably. After paralysis due to a ruptured lumbar disk, function can be restored because the lesion involves the peripheral nerves. Moreover, spontaneous healing of a ruptured disk must be unusual.

#### REPORT OF CASES

##### CASE 1—Rupture of fourth lumbar intervertebral disk into spinal canal

A laboring man aged 53 had had a sudden severe attack of "sciatica" on the right side and pain low in the back five years before that kept him in bed over three months. His recovery was slow, covering a period of three months.

Thirteen months before, while he was shoveling sand, a pain (not very severe) stabbed him in the lower part of his back. As he continued at work the pain became intense and was increased by movement. Two days later, while he was at work, "something gave way in his back" and the pain became excruciating. He went to bed, and in the afternoon control of his bladder became difficult and then impossible.

1. Dandy, W. E. Concealed Ruptured Intervertebral Disk for the Elimination of Contrast Mediums in Diagnosis. *J. N. A.* 821 (Sept. 6) 1941, Loose Cartilage from Intervertebral Disk. Tumor of the Spinal Cord, *Arch. Surg.* 19:660 (Oct.) 1927.

four days he could not pass urine and was catheterized. The pain was unbearable and he was unable to get out of bed. Morphine was given repeatedly. On the fourth day the pain was somewhat improved, he was able to get up but could not use his right leg. The urine then began to dribble but retention still made catheterization necessary. There was also fecal incontinence.

By degrees the pain lessened but an infection of the bladder kept the patient in a hospital seventy-eight days. During this period he noticed numbness in the back of both legs but the motor power in the right leg improved so that he could walk although with difficulty. The disturbance and anesthesia of the bladder and rectum were still present when he was admitted to the Johns Hopkins Hospital one year later. The infection in the bladder had cleared despite continued intermittent use of the catheter.

Examination on Dec. 19, 1941 revealed (1) weakness of the flexor and extensor movements at the right foot (2) bilateral anesthesia of all nerve segments on the right below the fourth lumbar vertebra including (3) saddle anesthesia and (4) anesthesia of the penis and the scrotum (5) loss of both Achilles tendon reflexes and (6) only slight response of the rectal sphincter.

This patient was presented at ward rounds with the students and an unequivocal diagnosis of ruptured intervertebral disk with compression of the lumbar spinal nerves was made. No

ing entirely across the spinal canal. The dura was then opened below the scar and the incision continued upward to it. The intradural scar was about 0.5 cm wide and very dense and had two distinct components; there were three small pure white glistening nodules, each about 3 mm in diameter, one far over to the left side of the dura on its dorsal aspect and the other two with a dumbbell formation on the right lateral aspect of the inner dura. These little white nodules were tightly bound together with the usual dense brownish red connective tissue of a scar. The mass clearly did not contain neoplastic elements. Three sensory nerve roots passed through the dense fibrous mass, and two had to be excised with it. Curiously this transverse fibrous mass was on the dorsal aspect of the spinal canal, the motor roots could be seen beneath and were intact after removal of the scar. On the right side the dura was an integral part of the scar and retained none of its normal appearance. The vertebral disk was then inspected. The posterior spinal ligament was a dense white scar but there was no localized protrusion, and when it was incised with a scalpel there was only very hard tissue beneath. The disk itself had, therefore, healed spontaneously after extrusion of the disk.

There could scarcely be a doubt that the scar throughout the interior of the spinal canal was the end product of the rupture of a disk into the spinal canal. And it was suspected that the small white glistening bodies in the scar represented actual remains of the extruded cartilage. In the stained microscopic sections cartilaginous remains were disclosed, some fairly normal and others so greatly disintegrated that only suggestions of cartilage were in evidence.

The patient left the hospital on Jan. 10, 1942, entirely relieved of pain and with some diminution in the anesthesia.

#### CASE 2—Rupture of sixth cervical disk with necrosis of spinal cord

A man aged 29 entered the hospital Jan. 2, 1942 and was operated on a few hours later. He was totally paralyzed in both legs and partly paralyzed in both arms and had bladder retention and loss of rectal control. Breathing was labored and was reinforced by use of the sternocleidomastoid muscles. There were rales in the lungs and much mucus which could not be delivered. The temperature was 104.2 F, the leukocytes numbered 18,000 and a patch of pneumonia in the base of the right lung was suspected because of clinical signs and its presence confirmed by roentgenogram twenty-four hours later.

Forty-eight hours before the time of operation the patient was seemingly perfectly well in every way. While straining at stool he suddenly became paralyzed to the degree noted, and all sensation was lost below the neck. All this paralysis developed within a few seconds, it appeared to begin in the left foot, went to the right and passed upward like a flash. Thirty-six hours later the condition showed no improvement, the patient was then rushed by ambulance from a neighboring city.

Examination showed complete motor and sensory paralysis with a sharp sensory level at the sixth cervical segment. The patient was perfectly conscious but apprehensive and somewhat panicky because of the embarrassed respirations.

It was possible to obtain a history of pain in the neck and shoulder over a period of six or eight months, always intensified by throwing a ball or moving the neck. The pain had probably been somewhat less during the past month. I suspected an extradural or intradural encapsulated tumor (probably a meningioma) because of the past history of pain and the associated sudden paralysis following straining at stool. In a case reported several years ago<sup>2</sup> this sequence of events was regarded as pathognomonic of an encapsulated tumor, and it has since been found to be a trustworthy sign. A ruptured intervertebral disk was not suspected.

At operation with the patient under local anesthesia, a cervical laminectomy was performed. At the level of the sixth cervical vertebra a sharply defined lesion was encountered. For a distance of perhaps 2 cm the cord was reddish brown, the vessels on the surface were enlarged and, for a moment an aneurysm was considered. The cord was dis-

Fig. 1 (case 1)—Operative sketch showing intradural scar wrapped around the posterior roots of the cauda equina. Note the three little isolated fragments of intact cartilage (1 2 3). Sketch representing the cross section of the scar in the spinal canal.

other diagnosis could be considered. My assistant, Dr. Troland, whose diagnostic acumen is almost perfection, was gently chided for having entertained the diagnosis of a tumor of the spinal cord and injected 1 cc of iodized oil. This was our second spinal puncture and injection of iodized oil in 100 cases of ruptured intervertebral disk—a procedure that we have denounced for ruptured lumbar disks as unnecessary, misleading, painful and harmful. Roentgenograms with the iodized oil showed a complete block at the fourth lumbar disk.

We had assumed that the situation revealed at operation would be similar to that in other cases in which the protruding extradural disk was so large that the cauda equina had been compressed by the extradural mass. One exceptional objective observation, however, was noteworthy, i.e., the sensory loss was much greater than the motor, whereas the reverse would have been expected.

At operation (fig. 1) on the following day the usual unilateral approach was made. The fifth ligamentum flavum was reflected on a hinge and replaced when the subdural space was seen to be normal. Exploration of the fourth subflaval space immediately revealed a scar so dense that exposure beneath the dura was impossible. Removal of a notch in the upper part of the fifth lamina showed the same impenetrable scar. The only safe approach then was to expose the dura by a complete laminectomy. On the dorsal surface the dura became more normal and was opened. At the level of the fourth lumbar interspace a dense scar was encountered extend-

tinctly swollen, had iodized oil been injected (it was not) a block would probably have been shown. When the leptomeninges were stripped an area of pinhead size in the center looked almost transparent and was nicked with a knife, a large amount of the necrotic interior of the spinal cord oozed from the opening (fig 2). The incision was extended almost the length of the lesion, and an increasing volume of necrotic material was spontaneously extruded. It contained no blood or fluid and was not even blood tinged, it was grayish white. It should be noted that a network of vessels extended up and down for some distance in the outer layer of the arachnoid membrane, indicating a vascular support to the contiguous lesion in the cord. It is known that the white matter in the brain and spinal cord is much softer than the gray matter and, therefore, far more susceptible to trauma. It being evident, therefore, that this was a traumatic lesion, the cause was

with severe pains in the chest, a diagnosis of pneumonia had been made (probably erroneously). Five weeks before he had had a temperature of 103 F. During a stay of three weeks in another hospital the diagnosis of sinus infection was made. He was discharged, apparently well. Shortly thereafter there were some stiffness of the neck and some difficulty in bending forward. Two weeks before admission severe pains in the chest returned and radiated to both shoulders. Any movement intensified the pains, but they were not aggravated by coughing and sneezing. About the same time both legs became weak, and he could not walk. There were also urinary infrequency and dribbling. Within twenty-four hours the paralysis of the legs became almost complete. Examinations revealed (1) some pain on pressure over the first and second thoracic vertebrae, (2) almost total paralysis of both legs, (3) sharp sensory loss at the level of the third

thoracic vertebra, (4) paralysis of the abdominal and the lower intercostal muscles, (5) extreme hyperactivity of the knee kicks and ankle jerks, (6) presence of the Babinski sign bilaterally, (7) loss of the position and the vibratory sense in the legs, (8) presence of the Queckenstedt sign (complete block), (9) a count of 50 cells (lymphocytes) in the spinal fluid, (10) a complete block at the second thoracic vertebra as shown with iodized oil (roentgenograms of the spine were normal) and (11) a temperature of 100 F.

The tentative diagnosis was epidural abscess or tubercle. A ruptured disk was not considered.

At operation on February 13, performed by Dr. Troland, rupture of the second thoracic vertebral disk was found. One large and many small pieces of cartilage were removed.

The paralysis was unimproved on March 11, 1947, but on May 1 there was decided improvement, the patient being able to take steps.

#### COMMENT

Among perhaps 300 operations for ruptured

intervertebral disks these are the only instances of such complications, except our first 2 previously reported cases, and none, I think, have been reported in the literature. Although these complications are relatively uncommon, the quick succession of these 3 cases indicates that they are probably to be expected more frequently in the future.

Spontaneous resolution of ruptured intervertebral disks has been suspected from the history of patients whose signs and symptoms appeared to indicate the existence of a ruptured disk and later disappeared. The usual history is one of recurrent attacks with intervals varying up to several months or years. However, it is my belief that a spontaneous cure is infrequent and occurs only after a period of many years. In case 1

Fig 2 (case 2)—A, the cord with the necrotic interior beginning to protrude at the surface. B, section of the cord removed to show the dura bulging because of rupture of the intervertebral disk. C, a drawing of the cord to show the effects of compression by the disk. D and E, cartilage removed from the bulging disk. F, diagram showing the effect of the lesion on the cord, note the extent of the necrosis of the interior of the cord. G, transverse section of the affected disk, showing the extent of the necrotic interior. H, cross section of a normal disk for comparison with the affected disk (G).

sought beneath the cord by gently retracting it. A rounded hard mass was seen bulging beneath the dura, which did not appear thickened or abnormal. An extradural search quickly revealed the protruding disk. When it was incised several pieces of cartilage extruded spontaneously, more were removed with forceps.

There appeared to be no possibility that return of function could follow so much necrosis of the interior of the cord. With administration of sulfathiazole the pneumonia cleared, but the patient died ten days later of paralysis of the respiratory tract. Examination of only the cervical portion of the cord and vertebrae was carried out.

#### CASE 3—Rupture of second thoracic disk with paraplegia

A Negro man aged 42 was admitted to the medical service Feb 11, 1942 complaining of pain in the neck and inability to walk. The present illness had begun two months before

lesion in the disk had remained dormant for four years and then had sprung up anew from the effects of the trauma incident to heavy lifting. This is the common story. I have suspected but cannot prove that a permanent cure results only when the protruding cartilage actually ruptures through the posterior ligament, where it is gradually absorbed. The reason for such a conception is the course of events after operation. It is now known that the important part of operative treatment is the adequate opening of the returning posterior spinal ligament which permits the eventual extrusion of the defective cartilaginous content of both the disk and the protrusion. The actual removal of a cartilaginous sequestrum doubtless hastens the healing and cure, but rarely it ever can all the defective disk be removed, and frequently, particularly if the disk is concealed, few or none of the fragments are removable without the inducing of an inadvisable degree of trauma. An adequate opening of the ligamentous cover is, therefore, the indicated treatment. This is probably the reason that ruptured disks are not found after severe crushing injuries of the spine or soon after dislocation, i. e., the posterior spinal ligament is torn and permits the injured disk to extrude spontaneously.

The high percentage of permanent cures which follow operation and are without sequelae therefore suggests that the extruded cartilage eventually is absorbed and disappears. Only twice have I seen at operation actual spontaneous rupture of the posterior spinal ligament with freely lying cartilage in the extradural space. I suspected that had operation not intervened a spontaneous cure might have resulted, but it is probable that the trauma (bending the spine) incident to lifting the patient to the operating table may have induced the rupture, in both instances the rupture through the spinal ligament could not long have antedated the operation. In case 1 the acute pressure of the protruded disk eroded the overlying dura and permitted its penetration into the spinal canal—an unusual sequel and almost a cure. Had the protrusion remained extradural a cure would probably have resulted. The long preservation of cartilage in the spinal canal and its incorporation in the scar indicate the disposition of an autogenous graft of cartilage in this situation.

In case 2 a successful result with restoration of spinal functions could not have been possible after the lapse of much time—probably a few hours. Once necrosis of the interior of the cord had begun the loss of function could only be rapidly progressive and permanent. The optimum time for the diagnosis and treatment, therefore, was before the spinal cord had been compressed with such abrupt suddenness. It is true that at the time of operation rupture of a vertebral disk was not suspected, but had the patient been seen earlier and an opportunity of study been provided it would probably have been suspected. Rupture of a cervical disk is far less common than rupture of a lumbar disk (in 10 of our 300 cases the ruptured disk has been in the cervical region), but it is sufficiently frequent to be considered seriously when a patient complains of pain in the neck—especially in the lower part of the neck—the shoulders and the arms. In all our cases the rupture has been at the sixth or the seventh cervical disk.

A postmortem examination in case 2 revealed only the cortical shell of the spinal cord remaining at the level of the rupture. When held to the light it was transparent for a distance of about 2 cm. A large cavity extended up and down the center of the spinal cord from the top of the fifth cervical vertebra to the top of

the second thoracic—a distance of four vertebrae! This cavity was due to the extension of the necrosed spinal cord along the path of least resistance extrusion through the meningeal covering is the more resistant course. The ruptured disk, as large as a hickory nut, pushed the dura posteriorly and in the exact midline. The entire center of the disk was loose cartilage, about one third of the entire disk being grossly destroyed. The area of necrosis extended through the anteroposterior extent of the disk, a seemingly normal cushion remained on each side. The lateral position of so many disks had prepared us to believe that the nucleus pulposus has nothing to do with the development of a ruptured disk. This specimen, however, which I believe is the only one reported post mortem, suggests that the destruction of cartilage did and probably always does begin in the nucleus pulposus. The greater frequency of lateral protrusions doubtless is explained by the looser attachment of the posterior spinal ligament to the vertebral body on the sides than in the center. Moreover, the ligament is definitely thicker in the middle. The much tighter binding of the ligament in the center is easily and strikingly demonstrated by stripping it with forceps. Eventually, however, the pressure beneath the ligament may become great enough to force the central attachment also, as in this case.

#### CONCLUSIONS

1 Though not frequent (occurring in 6 of 300 cases, an incidence of 2 per cent), serious sequelae resulting from rupture of an intervertebral disk produce severe loss of function referable to the spinal cord or the cauda equina (depending on their site).

2 A ruptured disk in the cervical or the thoracic region is a potential source of permanent destruction of the spinal cord. Its diagnosis and treatment before involvement of the spinal cord is of permanent importance. The diagnosis is suggested by localized and referred pain. After the spinal cord is involved operative treatment within a few hours is imperative if any function referable to the spinal cord is to be expected. Iodized oil is indicated for an early diagnosis when the spinal cord is involved, i. e., when the ruptured disk is in the cervical or the thoracic region. It is not indicated for rupture of a lumbar disk because with rare exceptions the diagnosis can be made with much more accuracy and certainty without it.

---

**Old Age and Change of Habits**—The mental hygiene of old age is often a crucial factor. Lucky is he who possesses that asset invaluable in senility, a cheerful disposition. The aged must endeavor by every means to curb emotion, promote equanimity and maintain contact with the outside world. Nature checks the emotional life, but this recession must be turned to advantage and not give way to indifference and selfishness. The ability to keep young requires training and exercise, it is the duty of those around the old to support their morale, to encourage their self respect and to convince them that they are loved and useful. As old trees cannot stand transplantation, so old people find it arduous to weather changes of habit and routine. The growing rigidity and unadaptability of the regulatory mechanism produce an automatism in senility which reacts with distinctly deleterious effects to the death of the marital partner, change of residence, retirement or other environmental modifications. Since this progressive automatism is inevitable and irreparable, it is advisable, as far as possible, to avoid habit deviations in senescence unless the change is specifically indicated or unavoidable.—Mueller-Deham, Albert, and Rabson, *S. Milton. Internal Medicine in Old Age*, Baltimore, Williams & Wilkins Company, 1942.

# SUBACUTE BACTERIAL ENDOCARDITIS DUE TO STREPTOCOCCUS VIRIDANS

A SURVEY OF THE PRESENT STATUS OF THE PREVIOUSLY REPORTED CURES AND A CLINICAL STUDY OF FIFTEEN TREATED CASES, INCLUDING ANOTHER CURE

CARTER SMITH, MD  
H CLIFF SAULS, MD  
AND  
CHARLES F STONE, MD  
ATLANTA, GA

Previous to the advent of the sulfonamide drugs recovery from Streptococcus viridans subacute bacterial endocarditis was exceedingly rare (table 1). The incidence of spontaneous cure, averaging all reported group studies, is 1 per cent.<sup>1</sup> Libman's series<sup>2</sup> of 150 patients with 3 per cent spontaneous recovery is the most favorable report. Lichtman and Bierman<sup>1</sup> have recently compiled the serial studies of six workers comprising a total of 634 patients. There were six spontaneous recoveries in this group. All patients in these groups were studied before the sulfonamide era.

TABLE 1—Recovery Rates in Subacute Bacterial Endocarditis with Different Forms of Therapy (from All Medical Literature)\*

|   | Number of Cases | Recoveries |            |
|---|-----------------|------------|------------|
|   |                 | Number     | Percentage |
| 1 Nonspecific treatment or spontaneous recovery | 634             | 6          | 1          |
| 2 Chemotherapy alone                            | 198             | 12         | 6          |
| 3 Chemotherapy with heparin                     | 43              | 5          | 11.5       |
| 4 Chemotherapy and hyperthermia                 | 25              | 4          | 16         |
| 5 Chemotherapy and intravenous typhoid          | 21              | 4          | 20         |

\* Only group studies are included in this table. Isolated reports of cases in which recovery occurred are omitted because the percentage of recovery could not be estimated.

Interest in the treatment of this almost universally fatal disease and enthusiasm over the newer therapeutic procedures with the sulfonamides have given rise to many reports in the literature in recent months.

In the earlier part of the sulfonamide era (1936 to 1939) chemotherapy was used without such adjuncts as heparin, neoisphenamine and hyperpyrexia. During this period, 198 patients were treated by eleven groups of workers with twelve recoveries, an average of 6 per cent (table 1).

In 1939 Kelson and White<sup>3</sup> first advocated the use of heparin with the sulfonamides. Since this time 43 cases treated by this method have been reported by three groups of workers<sup>1</sup> with a recovery rate of 11.5 per cent. More recent reports, however, are less favorable.<sup>4</sup> Heparin is both expensive and dangerous, and

the advantage of using it in the treatment of subacute bacterial endocarditis does not at the present time seem to outweigh its disadvantages.

In 1939 H. J. White<sup>5</sup> demonstrated an increase of one hundred fold in the bactericidal properties of sulfanilamide with an increase in the temperature from 37 C to 39 C (99.2 F to 102.2 F). Occasionally, before and since this observation attempts have been made to treat subacute bacterial endocarditis with hyperpyrexia and the sulfonamides. Lichtman and Bierman<sup>1</sup> have collected the reports of 25 cases from three clinics in which hyperthermia induced by diazepam and the sulfonamides were given. The recovery rate in this small group was 16 per cent (4 cases).

The sulfonamides with artificial fever induced by intravenous typhoid-paratyphoid injections have been used by Solomon<sup>6</sup> and others. Of 21 patients treated by this method, 4 have recovered, a recovery rate of 20 per cent, the highest of any reported group.

A follow-up study of the cases in which recovery has occurred after subacute bacterial endocarditis due to Streptococcus viridans that have been reported in the medical literature since the advent of the sulfonamides has been attempted. Letters were sent to thirteen authors, who have reported a total of 35 cases in which recovery occurred. Answers were received from all. The results will be chronologically considered.

In 1938 there was 1 recovery reported.<sup>7</sup> The patient suffered cardiac failure and died a few months later. Autopsy showed complete healing of the recent endocarditis.

In 1939 12 recoveries were reported.<sup>8</sup> The periods of observation of these cases ranged from twenty-five to thirty-six months. Only 1 of these 12 patients is dead. This patient died of congestive heart failure six months after the subacute bacterial endocarditis had been clinically cured; autopsy revealed complete healing of the endocarditis.

In 1940 there were 10 instances of recovery added to the literature.<sup>9</sup> Nine of these patients are living and well today with observation periods ranging from one to three years. One of these patients was observed only three and one-half months after apparent cure and no follow-up is available.

In 1941 there has so far been reported (some not yet published) 12 recoveries.<sup>10</sup> The period of observation in this group of patients varies from eight months to three years, and all are living and well except 1. This patient was killed in an automobile accident five months

after surgical ligation of the patent ductus arteriosus. Postmortem examination showed the ductus to be completely closed and no vegetations could be found.

Of the 12 reported cures for 1941, 4 resulted from surgical ligation of an infected patent ductus arteriosus.<sup>11</sup> Sulfonamide therapy was used in conjunction with the surgical procedures. Observation on these 4 patients was from eight months to twelve months.

#### A CLINICAL STUDY OF FIFTEEN PATIENTS WITH SUBACUTE BACTERIAL ENDOCARDITIS

Fifteen cases of subacute bacterial endocarditis due to *Streptococcus viridans* were studied. This group

The usual drug reactions were encountered. Lack of clinical and cultural response, together with drug intolerance accounts for the periods of omission in therapy and the variety of chemotherapeutic agents employed. Transfusions were carried out in all as a supportive measure. 1 patient receiving a total of forty-five during his nine months of illness terminating in death. Large amounts of vitamins and iron were given as indicated. In 1 patient neocarsphenamine was used with sulfathiazole and a persistent, severe, peripheral neuritis developed. Heparin, maintaining a clotting time of one hour had been previously used for 1 patient who suffered a cerebral embolus during that

comprises all such cases from Piedmont Hospital (12 cases) and Emory University Hospital (3 cases) in which sulfonamide therapy has been given up to the present time Nov 1, 1941.

#### GENERAL OBSERVATIONS

The average age was 41 years with the youngest patient being a girl of 16 years and the oldest being a man of 71. In general, the younger patients tolerated the chemotherapeutic agents much better than the older group. Sulfadiazine seemed the most acceptable sulfonamide to the older patients.

period. Three other patients not on heparin experienced major embolic phenomena—radial, pulmonary and popliteal. All 15 had minor episodes. The spleen was palpable in only 7 cases.

The average interval between the onset of symptoms and the institution of chemotherapy in this group of 15 was twenty-four days, with the shortest period seven days and the longest eight months. A frequent initial chief complaint of the patient was that he had the "flu." An acute respiratory infection coincided with the prodromal symptoms of 3 patients. Two patients insisted that they were well until they underwent a tooth extraction, and 1 first noticed a gingivitis six days before systemic symptoms became manifest. Another patient

11 Gross R. E. Surgical Closure of the Patent Ductus Arteriosus. Modern Concepts of Cardiovascular Disease No. 12, 10, 6 (Nov.) 1941. Merrill Arthur and Elkin Dan. Personal communication to the authors.

was subjected to intradermal alleigy tests the day of onset The remaining 9 patients offered no clue as to the possible port of entry for the infection

RESULTS

Of these 15 patients, 10 were dead on an average of six and seven-tenths months after the first symptom, the shortest interval being two months and the longest interval twelve months Eight of these 10 patients came to autopsy Underlying rheumatic damage was found in 5 of these 8 patients, congenital pulmonary stenosis in 1, only arteriosclerotic changes in another and infection superimposed on an old syphilitic aortic valvulitis in another This last finding is quite rare, only 4 similar infections with *Streptococcus viridans* having been previously reported<sup>12</sup>

All postmortem examinations revealed splenic and renal infarcts except in 1 case This patient had an

and Dan Elkin) The other patient with apparent cure has had no surgery and remained well nineteen months after discontinuing drug treatment Details of this case follow

REPORT OF CASE IN WHICH RECOVERY OCCURRED

A girl aged 16 years with an asymptomatic patent ductus arteriosus had been under observation since she was 10 A check-up was made at yearly intervals and there had been no evidence of progressing myocardial disease during this time

One month before the onset of the present illness the patient was seen because of the sudden development of a raised black "mole" on her right thigh This was removed by wide surgical excision (Dr Perrin Nicholson) on Dec 16, 1939 The pathologic report on this specimen was hemangioma Recovery was uneventful

The patient was next seen on Jan 17, 1940, one month later, at home At this time there was an influenza epidemic in the

community She presented the clinical picture of fever, aching and a negative physical examination other than the previously noted signs of a patent ductus arteriosus During the first five days, fever was intermittent, the temperature ranging from 99 to 104 F At this time a small petechia was found in the left lumbar region A blood culture made on this day was positive within twenty four hours for *Streptococcus viridans* A second blood culture five days later was positive within forty-eight hours for the same organism

The patient was well developed and well nourished There were no other petechial manifestations and the only abnormal physical finding was a continuous machinery murmur with a systolic thrill over the second and third left inter costal space There was no cardiac hypertrophy except a prominent pulmonary conus The lungs were clear throughout, and the spleen was not palpable

Previous electrocardiographic studies were normal and teleroentgenograms showed only a prominent pulmonary conus A complete blood count was normal except for 11,300 white cells on January 22 and 21,700 white cells on January 26 The differential blood studies were normal Urinalyses were

negative except for occasional red blood cells in the sediment Blood cultures were positive on four occasions for *Streptococcus viridans*

One week after the onset of the present illness sulfanilamide<sup>13</sup> was begun She received on successive days 40 grains (2.6 Gm) 100 grains (6.5 Gm) and 80 grains (5.2 Gm), then 60 grains (4 Gm) daily for six days Fever persisted, but at a lower level On January 31, two weeks after the onset of the present illness, the patient was admitted to the hospital Intravenous sulfanilamide 15 grains (1 Gm) every twelve hours was given in addition to 15 grains by mouth every six hours Blood sulfanilamide concentration on this dose reached 41 mg and there was an appreciable reduction in the temperature curve By the eighteenth day of continuous treatment a secondary anemia developed, and sulfanilamide was discontinued for five days During this time two transfusions were given and 100-voltage roentgen therapy in eleven treatments of 535 r over the second and third left intercostal spaces was given

Blood cultures taken during sulfanilamide therapy on January 31 and February 3 had become negative, but three days after cessation of the sulfanilamide (February 12) the culture again was positive for *Streptococcus viridans*

Hospital record of patient with subacute bacterial endocarditis

infection superimposed on a congenitally stenotic pulmonary artery, and embolic phenomena were limited to the lesser circulation

Five patients remain alive, 3 with evident persistent disease and 2 without Each of the 3 patients with persistent symptoms have rheumatic heart disease Two of these patients received "adequate" therapy with sulfathiazole, sulfapyridine and sulfadiazine Details are lacking in the third but the prognosis in all is equally unfavorable

Two of the 15 are living and apparently well In each of these the streptococcal infection was superimposed on a patent ductus arteriosus In 1 the ductus was ligated successfully by Dr Dan Elkin on June 16, 1941, and the patient remained well four and one-half months after discontinuance of chemotherapy (to be reported in detail at a later date by Drs Arthur Merrill

12 Braunstein, A L, and Townsend, S R Bacterial Endocarditis on Superimposed Syphilitic Aortic Valvulitis Arch Int Med 65 957 (May) 1940

Two transfusions restored the red blood cell count to 5,400,000, and sulfanilamide therapy was resumed on February 19. The dose was started at 100 grams by mouth in twenty-four hours. This was gradually increased to 190 grams (12 Gm) daily and the blood concentration ranged between 5 and 9.1 mg per hundred cubic centimeters. Eight days after beginning this dosage of sulfanilamide the patient became afebrile and the blood cultures again were negative.

On March 1 after one month's stay in the hospital she was given a transfusion for the third time and allowed to go home. There sulfanilamide therapy was continued 180 grams (11.6 Gm) daily for the next two months. During this two-month interval blood counts, blood cultures, blood sulfanilamide levels and urinalyses were done once or twice each week. She remained afebrile. Two other transfusions were given during the two months but in general the drug was tolerated without difficulty and the patient complained bitterly of not being drunk any more after the drug was completely withdrawn on May 1. A total of 894 Gm was given during this period of seventy-three days of continuous therapy.

Since May 1 she has received no chemotherapy and repeated blood cultures have been negative. Twenty-nine months have now elapsed since the last positive blood culture and today (May 15, 1942) she is clinically well. There has been no detectable change in the heart murmur, heart size or contour or in the electrocardiograms when compared with those recorded before the onset of the subacute bacterial endocarditis.

During the past year she has enjoyed a normal high school existence and has gained 16 pounds (7.3 Kg). In February 1941 she contracted whooping cough but the severe coughing paroxysms of several weeks duration did not precipitate a reinfection of the healed endocarditis.

The patient's excellent clinical response to sulfanilamide therapy was probably due to its early administration and to the long-continued administration of large doses. The drug was able to exert its bactericidal effect on the organisms before the 'fibrin-platelet mass' formed a protective coating over the colonies.

#### COMMENT

As has been pointed out by Christian,<sup>13</sup> a most important factor in the treatment of these patients with the sulfonamides is early diagnosis. It has been shown<sup>14</sup> that the bacterial colonies have thrown about themselves a fibrin-platelet protectorate that is practically impervious to the sulfonamides. If this protective wall has had sufficient time to become thick enough to prevent access of the drug to the bacteria, cure is obviously almost impossible. In our case the clinical manifestations of the disease were not of over one week's duration before sulfanilamide therapy was begun.

A second factor of importance is the maintenance of a high blood concentration of the drug. A 10 mg concentration of the blood stream has been arbitrarily determined the optimum level.<sup>15</sup> This requires a variable dosage of the drug, as individual absorption and clearance may be different. In our case, 180 grams of sulfanilamide daily was required to maintain a satisfactory blood concentration.

Intolerance to the drug is a disturbing factor complained of by many patients. This is eliminated largely

now by the more easily tolerated sulfadiazine. Even with this relatively pleasant drug such idiosyncrasias as blood dyscrasias and renal complications may occur.

In evaluating the therapeutic effect of the sulfonamides, it must be remembered that sulfapyridine may exert an antipyretic effect<sup>16</sup> and in this way lower the temperature without appreciably decreasing the infection. False therapeutic optimism may arise from this phenomenon. Likewise, blood cultures may fail to show bacterial growth after the sulfonamides have been given, even though infection is still present. This error may be avoided by adding para-aminobenzoic acid to the culture mediums to neutralize the bactericidal effect of the sulfonamide present in the blood specimen being cultured.<sup>17</sup>

At this time, it seems that a combination of sulfapyridine or sulfadiazine therapy, protein shock and artificially induced fever with intravenous typhoid-paratyphoid vaccine offers the most favorable therapeutic approach to this disease.

Solomon<sup>18</sup> is now administering typhoid-paratyphoid vaccine in 1,000 cc of isotonic solution of sodium chloride and 5 per cent dextrose either slowly or rapidly, depending on the height and the duration of the fever desired. The intravenous typhoid therapy is begun on the night of the second day after sulfapyridine therapy has been instituted. Two Gm is given for the first two doses and then 1 Gm thereafter at four-hour intervals. One-half minim (0.03 cc) of the typhoid vaccine is given in the saline-dextrose solution, and this dose is repeated in one to two hours if necessary to maintain the temperature level above 104 F for at least three hours continuously. The injections are continued nightly several hours after the last meal for seven to ten days. The amount of the vaccine is increased as necessary to maintain the desired level of temperature. Sulfapyridine is usually continued for at least one week after vaccine therapy has been discontinued.

Accessory therapeutic measures such as fluids, adequate nourishment, vitamins, sedatives and transfusions are carried out in addition to specific therapy. Examinations of the blood and urine are performed at frequent intervals in order to ascertain the drug level in the blood and to detect evidences of drug intoxication.

#### CONCLUSIONS

1 There has been a gradually decreasing mortality rate in subacute bacterial endocarditis since the advent of the sulfonamides.

2 The literature has been searched for authentic instances of cure of subacute bacterial endocarditis due to *Streptococcus viridans* and 35 reports were found. The authors of these reports were written to and follow-up notes to date have been obtained.

3 The clinical records of 15 patients treated by several physicians at the Piedmont Hospital and Emory University Hospital which have been tabulated show that there were 2 patients who recovered in this group.

4 Various therapeutic procedures have been used in combination with the sulfonamides including heparin, neosarsphenamine, hyperpyrexia by diathermy, and hyperthermia with typhoid-paratyphoid vaccine. The

latter is most recent and in a small series of cases has afforded the best recovery rate. Because of increased tolerance without decreased efficiency, sulfadiazine with intravenous typhoid is probably the method of choice at the present time and should receive extensive clinical trial.

5 Clinical trial on larger groups of patients with the combined use of sulfadiazine and the intravenous use of typhoid-paratyphoid vaccine should be carried out. This method has so far offered the best recovery rate, but the number of patients treated in this manner is too small to justify final conclusion at this time.

6 Surgical ligation must be considered for those patients having patent ductus arteriosus associated with subacute bacterial endocarditis.

## LUMBAR PUNCTURE

ITS POTENTIAL ROLE IN THE PRODUCTION OF  
INJURIES TO THE INTERVERTEBRAL DISK

DONALD MUNRO, M.D.

AND

WARREN G. HARDING, M.D.

BOSTON

The use of lumbar puncture in the investigation of lesions of the central nervous system has become so standardized that it is almost as much of a routine procedure as the systematic study of the reflexes. The saying that "familiarity breeds contempt" may be aptly applied to this procedure, for one seldom considers that there is any real danger associated with its use. Many thousands of punctures have been done by the staff of the department of neurosurgery in the Boston City Hospital during the past ten years and, as far as is known, the occurrence of headache during the ensuing one to three days has constituted their only complication. It may be well, however, at this point to emphasize that the presence of space-occupying lesions within the cranial cavity, as suggested either by the history or by the physical findings including an examination of the optic disks, constitutes a definite contraindication to its use.

During recent years the role of herniation of the nucleus pulposus in the pathogenesis of low back and recurrent pain in the sciatic distribution has been confirmed by many investigators. The fact that even small injuries to the annulus fibrosus may produce a hiatus through which the plastic nucleus pulposus can herniate has led us to reevaluate lumbar puncture as a possible etiologic agent in the production of this entity.

The intervertebral disk is composed of two distinct parts, namely the annulus fibrosus and the nucleus pulposus. The annulus fibrosus is a fibrous tissue structure derived from mesenchymal cells that migrate from the sclerotomes to surround the notochord at about the fifth week of embryologic development. The notochord, which at first is continuous throughout the length of the developing vertebral column, becomes segmented by about the second month. The expanding segments are either squeezed or migrate into the area occupied by the anlage of the developing intervertebral

disk, which at this stage consists of mesenchymal cells previously mentioned. The segments gradually lose their connection with one another, though remnants of this original connecting structure may persist. If they do persist they form a point of weakness which leads in later years to herniation of the nucleus into the body of the vertebra as described by Schmorl.<sup>1</sup> The further evolution of the mesenchymal cells leads to the development of a strong fibrous membrane, which is attached to the margins of the bodies of adjacent vertebrae and internally is intimately fused with the nucleus pulposus, for which it acts as a limiting membrane.

The intervertebral disks constitute one fourth of the entire length of the vertebral column. The mobility of the spinal column as regards flexion, extension and rotation is dependent on the plasticity of this structure. The extremes of movement are limited by the length of the spinal ligaments. It is at once apparent that flexion of the spine will simultaneously relax the anterior spinal ligaments and put the posterior ligaments on a stretch. The anterior portion of the annulus fibrosus will also be relaxed and the posterior section stretched to the same relative degree as the respective spinal ligaments. The fluidity of the nucleus pulposus serves to cushion the alterations in the pressure developed between the vertebrae in all these movements, while the annulus fibrosus acts as its limiting membrane. Any injury to the membrane, whether resulting from excessive stretching or from direct penetration, can be expected to weaken its limiting power and thus permit the plastic nucleus to protrude beyond the limits of the borders of the vertebral bodies. Anteriorly or laterally, such an occurrence will cause few recognizable or significant symptoms. If the nucleus is extruded posteriorly, however, because of the vertebral canal there will be encroachment on and subsequent distortion of the spinal nerve roots, particularly as they enter the intervertebral foramina, and the symptoms will be both significant and common. The greatest strain on the posterior ligaments will be found at the fourth and fifth lumbar and first sacral vertebrae where the lumbar curve is centered. It is at this point that clinically recognizable herniations of the nucleus pulposus most frequently occur.

It is unnecessary for our purpose to enter into a description of the further details of the anatomy and pathology of lesions of the intervertebral disk, as an excellent description of these features may be found in the recent monograph of Bradford and Spurling.<sup>2</sup> The experimental work of Bari<sup>3</sup> demonstrated that he could repeatedly distend the annulus fibrosus by compressing the intervertebral disk. There was always a return to normal subsequent to the release of the pressure except when the annulus fibrosus had been pierced by a needle, in which case herniation of the nucleus pulposus occurred. The same conditions present in his study are associated with the performance of a lumbar puncture. The flexion of the spine, which is the usual position of the patient during the operation

stretches the posterior portion of the annulus fibrosus and produces an associated increase in the tension of the nucleus while the lumbar puncture needle supplies the penetrating force.

The occurrence of injury to the annulus and nucleus by the spinal needle has been reported by several writers. In 1919 Levinson<sup>4</sup> noted that material from the disk might block the needle during puncture. Billington<sup>5</sup> studied 35 cases of back pain in which the clinical and radiologic evidence pointed to damage of the intervertebral disk by lumbar punctures done during the course of meningitis. Twelve cases showing clinical evidence of protrusion of the nucleus following lumbar puncture were reported by Pease.<sup>6</sup> The symptoms were characteristic and the interval between the puncture and the onset of symptoms was less than two weeks. Other cases have appeared in the literature, but those cited will suffice as a representative summary and to indicate that the inherent danger has long been recognized even though neglected.

In 1938 one of us<sup>7</sup> described a method of doing lumbar punctures in which it was advocated that flexion of the spine of the patient be abandoned. It was pointed out that such a position was of no actual aid in securing more room for the needle between the adjoining bones and indeed militated against easy puncture. This was because of the adverse physiologic condition engendered in a conscious patient who was held immobile and helpless while a strange and possibly painful procedure that he could not see was being carried out. The x-ray evidence to be adduced offers additional and equally important reasons for abandoning the custom of approximating the patient's neck and knees as a prerequisite to lumbar puncture or as a substitute for the patient's cooperation.

During the past year a two needle technic of myelography has been developed in the neurosurgical department of the Boston City Hospital. In the course of this procedure the spinal needles are permitted to remain in situ while the lateral spine plates are exposed. This has given us an opportunity to study such needles when in position in the subarachnoid space as regards their direction toward the intervertebral spaces. The punctures have all been done by members of the staff of the department. We have studied a consecutive series of roentgenograms containing fifty needles with the following results. Thirty-six per cent of the needles were in such a position that had they been inserted farther in the line of their course they would have penetrated the annulus fibrosus. The distance between the end of the needle and the surface of the annulus averaged between 4 and 5 mm. We explain the depth of the penetration of the needle beyond the anterior dura by a pushing of the arachnoid ahead of the point of the needle. This appears to be a factor which cannot be altered at present. One puncture was made between the eleventh and twelfth dorsal vertebrae. This needle was found directed away from the intervertebral space. Eleven needles were inserted between the last

dorsal and the first lumbar vertebra. In three instances the needle was directed toward the disk. In one of these the needle was only 2 mm from the surface of the annulus fibrosus. Eight needles were placed between the first and second lumbar vertebrae. Six were found directed in such a way that their projection would not have involved the intervertebral space. The three needles between the second and third lumbar vertebrae were all directed toward the bony wall of the body of the bone. The space between the third and fourth vertebrae appeared to be the most dangerous one in this series. Twelve needles were in this space. Nine, or 75 per cent were found directed toward the intervertebral space. Seven needles were inserted between the fourth and fifth lumbar spaces. The projection of the axis of three, or 42 per cent, of these was directed toward the annulus fibrosus. The two latter sets of figures are of particular importance in view of the fact that it is through these two spaces that the majority of lumbar punctures are done in clinical practice. The use of the interspace between the last lumbar and the first sacral vertebra appears from this study to be the safest one because only one of the eight needles photographed in this position was directed toward the dangerous area.

Our findings demonstrate that perforating injury to the posterior part of the annulus fibrosus is a distinct possibility during the course of lumbar punctures done without forced flexion of the spine and by men who are familiar with the procedure. The depth to which the needles have penetrated emphasizes the care that must be taken if perforation of the annulus fibrosus is to be avoided.

The series is too small to be statistically significant but suggests that the interspace between the last lumbar and the first sacral vertebra is the location of choice, and that the spaces between the third and fourth and the fourth and fifth lumbar vertebrae should be avoided whenever possible. We do not wish to imply that this form of injury is a frequent or major cause of herniation of the intervertebral disk but rather that it constitutes a mechanical possibility the danger of which must always be kept in mind.

# THE BLOOD CONCENTRATION AND URINARY EXCRETION OF SULFADIAZINE

FOLLOWING INTRAPERITONEAL ADMINISTRATION

JOHN D RYAN, MD

ELI BAUMAN, MD

AND

JOHN H MULHOLLAND, MD

NEW YORK

Since sulfadiazine has been shown, on oral and intravenous administration, to possess certain advantages over the other sulfonamide drugs (it is readily absorbed, is excreted comparatively slowly, is acetylated in blood and urine to a lesser degree, causes fewer toxic manifestations and is effective against a wider variety of pathogenic bacteria),<sup>1</sup> it seemed to us that this would be the drug of choice for intraperitoneal use in abdominal surgery. Although studies on the intraperitoneal use of sulfanilamide have been reported by a number of investigators,<sup>2</sup> we have been unable to find reports of the intraperitoneal use of sulfadiazine. We have studied the blood levels and urinary excretions of sulfadiazine following the intraperitoneal administration of the drug to determine the rate of absorption and hence the depletion of the local intraperitoneal store, since the advantages of this route of administration are dependent on the local concentration of the drug.

## MATERIALS AND METHODS

Six adult male patients were used in this study. The age, clinical diagnosis and operative procedures for each patient are shown in the accompanying table. At operation doses of sulfadiazine powder varying from 5 to 25 Gm, as indicated in the table, were sprinkled into the peritoneal cavity. On returning from the operating room each patient was catheterized and the catheter allowed to remain in the bladder. All urines were collected, the volumes measured and samples taken for analysis at various intervals following the intraperitoneal administration of the drug. At similar intervals samples of blood were taken from the median cubital vein and placed in bottles containing sodium oxalate. Following the initial intraperitoneal dose there was no further administration of any sulfonamide by any route. The sulfadiazine concentration in the blood and urine samples was determined by the method of Bratton and Marshall.<sup>3</sup> The fluid intake during the period of study was noted.

Dr Benjamin Carey of Lederle Laboratories, Inc., furnished the sulfadiazine used in this study.

From the Department of Surgery New York University College of Medicine and the Third Surgical Division Bellevue Hospital.

## RESULTS

The results are shown in the accompanying table. In the patient who received the 5 Gm dose of sulfadiazine, the free blood sulfadiazine concentration thirteen hours after the administration of the drug was 22 mg, the total 26 mg per hundred cubic centimeters, at thirty-four hours the free blood sulfadiazine concentration was 26 mg, the total 28 mg per hundred cubic centimeters, and at sixty hours the free blood sulfadiazine concentration was 13 mg, the total 13 mg per hundred cubic centimeters. The urinary excretion was not determined on this patient. In the 3 cases in which 10 Gm of sulfadiazine was given intraperitoneally the peak of the blood

Blood Concentration and Urinary Excretion of Sulfadiazine Following Intraperitoneal Administration in Six Cases

sulfadiazine level occurred at twelve hours in case 1 and at twenty-four hours in case 2. The highest level obtained was 56 mg per hundred cubic centimeters for free sulfadiazine and 61 mg per hundred cubic centimeters for total sulfadiazine (case 2). The lowest peak occurred

case 4 in which the free blood sulfadiazine was 45 mg per hundred cubic centimeters and the total 47 mg. The blood levels remained elevated in case 2 and case 3 for forty-eight hours and in case 4 for twenty-four hours. Detectable amounts were present in all cases for at least three days following the administration of the drug. In all cases the concentration of the drug in the urine paralleled the blood concentration, the greatest excretion occurring between twelve and twenty-four hours after the administration of the drug. The acetylated sulfadiazine in the urine rarely exceeded 30 per cent of the total urine sulfadiazine in all cases. In case 2 approximately 30 per cent of the drug was excreted in forty-eight hours and 40 per cent in seventy-two hours. The total fluid intake was relatively constant in all cases, the amounts for each six hour period being indicated in the table. The volume of urine excreted varied somewhat in each case as can be seen from the table, but the daily output was comparatively constant.

In the patient who received 20 Gm of sulfadiazine intraperitoneally, the blood sulfadiazine concentration reached its peak twenty-eight hours after the administration of the drug, the free sulfadiazine being 18.5 mg per hundred cubic centimeters and the total 20.7 mg. This level was maintained for fourteen hours, after which time it began to drop relatively slowly and at ninety-four hours the blood level was still elevated, the free blood sulfadiazine concentration being 3.2 mg per hundred cubic centimeters and the total 3.2 mg. There were detectable amounts of the drug present in the blood one week after it was administered. The concentration of sulfadiazine in the urine again paralleled that in the blood, the greatest excretion of the drug occurring between twenty-four and forty-eight hours after its administration. Again the acetylated fraction in the urine rarely exceeded 30 per cent of the total drug. The fluid intake was constant, as can be seen from the table. The volume of urine excreted showed some variation in each six hour specimen, but again the twenty-four hour output was relatively constant.

Following the administration of 25 Gm of sulfadiazine intraperitoneally in case 6 the blood sulfadiazine

the blood, the greatest excretion occurring between twelve and thirty-six hours after the administration of the drug. Exceedingly large amounts of the drug were excreted in the urine during the first sixty hours as can be seen from the table. Twenty hours after the administration of the drug the total urine sulfadiazine was 2.086 mg per hundred cubic centimeters and the free 1.537

Chart 2 (case 6)—Blood sulfadiazine level, urine sulfadiazine level, urinary output and fluid intake in a patient with ulcer of the stomach with partial gastrectomy, 25 Gm of sulfadiazine powder was given intraperitoneally.

mg. No sulfadiazine crystals were seen in this specimen. The volume of urine excreted again showed slight variation but was fairly constant over the twenty-four hour period. The fluid intake was maintained with slight variations.

#### COMMENT

The concentration of sulfadiazine in the blood following the intraperitoneal administration of the drug rises fairly rapidly and remains elevated for a considerable period of time, depending on the amount of the drug administered. With the administration of 10 Gm of the drug effective levels persist for approximately forty-eight hours, with 20 to 25 Gm for seventy-two to ninety-six hours. Thus one need not administer the drug by any other route for two to four days postoperatively and, in addition, one can be fairly certain that the local concentration of the drug in the peritoneal cavity remains high for the same period of time. Although we have observed no ill effects following the administration of the larger doses of the drug (20 to 25 Gm), it would appear that the administration of 10 Gm is satisfactory for the maintenance of adequate blood levels and high local concentrations in comparatively clean operative cases such as we have studied. In cases of gross contamination of the peritoneal cavity with widespread peritonitis one need not fear giving larger doses.

It can be seen from our results that sulfadiazine powder is readily absorbed from the peritoneum, although not as rapidly as from the gastrointestinal tract. Sadusk and Tredway<sup>4</sup> have shown that the peak of absorption of sulfadiazine given by mouth occurs between three and six hours. The peak of absorption in our cases occurred somewhat later, between twelve and thirty-six hours. The slower absorption of the drug from the peritoneum is to be desired so that the local concentration will remain elevated for a longer period of time. Keeley,<sup>5</sup> injecting a solution of sulfanilamide into the peritoneal cavity of dogs, obtained a peak

Chart 1 (case 2)—Blood sulfadiazine level, urine sulfadiazine level, urinary output and fluid intake in a patient with carcinoma of the stomach with partial gastrectomy, 10 Gm of sulfadiazine powder was given intraperitoneally.

concentration rose steadily until at eighteen hours the free sulfadiazine concentration was 9.1 mg per hundred cubic centimeters and the total 10.4 mg. This level was maintained for approximately twelve hours and then began to fall, and at ninety-six hours the concentration of both free and total sulfadiazine in the blood was 3.2 mg per hundred cubic centimeters. Here again the concentration of the drug in the urine paralleled that in

<sup>4</sup> Sadusk, J. F. Jr. and Tredway, J. B. Observations on the Absorption, Excretion, Diffusion and Acetylation of Sulfadiazine in Man. *Yale J. Biol. & Med.* 13: 539, 1911.

<sup>5</sup> Keeley, J. I. Intraperitoneal Administration of Sulfanilamide. Concentration in Peripheral Blood in Dogs. *Proc. Soc. Exper. Biol. & Med.* 46: 458, 1911.

of absorption in two to six hours Jackson and Collier,<sup>6</sup> using powdered sulfanilamide intraperitoneally, obtained the peak of absorption within four hours. Since the absorption of sulfadiazine from the peritoneal cavity is slower than that of sulfanilamide, we feel that it is the better drug to use for local intraperitoneal implantation.

## SUMMARY

Blood and urinary concentrations of sulfadiazine were studied in six cases after the intraperitoneal administration of doses of sulfadiazine powder ranging from 5 to 25 Gm.

With 10 Gm of sulfadiazine intraperitoneally effective blood levels of the drug were maintained for forty-eight hours, with 20 Gm for eighty-four hours and with 25 Gm for ninety-six hours.

There were no postoperative complications and no toxic manifestations of the drug observed in any of the cases studied.

## WESTERN EQUINE ENCEPHALOMYELITIS OCCURRING SPORADICALLY IN A METROPOLITAN AREA

## REPORT OF CASE

RICHARD B. RICHTER, M.D.

CHICAGO

All previously observed and properly diagnosed cases of the western form of equine encephalomyelitis in man have been encountered only in rural or semirural districts, usually in conjunction with large or small epidemics in areas in which there were or had been epizootics of the disease in horses. The case herein reported presents a unique exception to this epidemiologic rule in that the patient dwelt in the heart of an industrial area of a large city and had not been away from this environment for many years. No other cases of the disease are known to have occurred in the region.

H. A., a painter aged 49, unmarried living in Chicago, was admitted to the Albert Meritt Billings Hospital on Aug. 24, 1941. He had been well and working until three days before his admission when he noticed pain in the back of the head and neck. During the next two days he had diarrhea with frequent watery stools. The day before admission he had malaise and felt chilly. The following day he was feverish and his physician found his temperature to be 105 F. The diarrhea had ceased at this time. He did not have a sore throat or other symptoms of an infection of the upper respiratory tract.

On admission the pharynx was injected and there was a slight enlargement of the cervical lymph nodes. A rough systolic murmur was heard over the aortic area, less distinctly at the base. There was some diffuse abdominal tenderness. He was slightly drowsy and listless but there were no other neurologic signs and no evidence of meningeal irritation. The admission temperature was 105 F., the pulse rate 100 and the respiratory rate 24. The white blood cells numbered 15,000, 50 per cent of which were polymorphonuclear leukocytes and 45 per cent lymphocytes. The urinalysis was normal except for a few granular casts and white blood cells. Nose and throat cultures were not abnormal and there was no growth on repeated blood cultures. Roentgenograms of the chest showed clear lung fields. Agglutination tests against the usual pathogenic intestinal organisms were negative. The Wassermann and Kahn reactions of the blood were negative.

The temperature ranged between 103 and 105 F. for the first three days, 102 and 104 F. on the fourth and fifth days, and then slowly fell to normal by the sixteenth day of hospitalization. On August 27, the third hospital day, the clouding of the sensorium had increased, there was some mental confusion and a slight but definite stiff neck. The spinal fluid, examined for the first time, was under a pressure of 140 mm. There were 180 cells, almost all of which were lymphocytes. There was a faint trace of globulin, the Wassermann reaction was negative and the colloidal gold curve was 0011110000. The total protein was 49 mg. per hundred cubic centimeters and the sugar 83 mg.

On August 28 a neurologic examination revealed distinct mental clouding and disorientation. Responses to simple questions were not intelligible and he followed directions poorly and incompletely if at all. There was moderate rigidity of the neck and the Kernig sign was elicited on both sides. The optic fundi were hyperemic but there was no papilledema. There were no cranial nerve palsies and no selective weakness of the extremities, nor was there any gross incoordination of movements so far as could be determined. The activity of the tendon reflexes was variable, but all were present and equal on the two sides. Plantar and abdominal reflexes were normal. There were no obvious sensory disturbances. Continuous restless plucking movements of the fingers of both hands were observed and there was a coarse, irregular tremor during voluntary movements of either arm. There was a plastic type of resistance to passive movements of the shoulder, elbow, hip and knee joints, greatest in flexor groups and more severe on the left side. At times there was a cogwheel quality to this rigidity.

This state of affairs represented the greatest development of signs and symptoms. Within a few days the sensorium began to clear and in this respect he appeared normal by the fifteenth day. It was then noted that his face was somewhat expressionless. The rigidity of the arms and legs and the tremor of the upper extremities improved slowly and steadily but was still obvious at the time of his discharge from the hospital fifty-six days after the onset of his illness.

He was seen for the last time on November 4, when he felt very well. A slight jerky resistance to passive movements was still present at the right shoulder, elbow and hip and a fine irregular tremor persisted in the outstretched hands, more on the right side.

The results of a series of examinations of the spinal fluid are given in table 1.

TABLE 1—Results of Laminations of the Spinal Fluid

| Date    | Pressure,<br>mm. | Cells | Protein,<br>mg./100 cc. | Sugar<br>mg./100 cc. |

Repeated questioning elicited the information that the patient had not been out of the city of Chicago since 1924 and had not even been for a drive in the country during the summer of 1941. He had been employed continuously as a painter of Pullman cars from December 1940 until the onset of his illness. During the summer of 1941 the car was brought in from service all over the country. Most of the cars had been used for the transport of troops. They were cleaned and stripped before being painted. He did not remember ever having seen mosquitoes in the cars or at any time.

and intracerebrally with 0.03 cc of the same material. In none of these animals did significant symptoms develop.

The blood of the patient taken on the fourteenth day of the disease was tested for neutralizing substances against the virus of western equine encephalomyelitis. Blood taken in the sixth week after the onset of the illness was tested for protection against the viruses of St. Louis encephalitis and lymphocytic choriomeningitis. Strong neutralizing antibodies were found against western equine encephalomyelitis virus but there was no protection against St. Louis encephalitis or lymphocytic choriomeningitis as indicated in tables 2, 3 and 4.

These results were checked and corroborated through the courtesy of Dr. F. Howell Wright who using mouse protection tests, found that the patient's serum protected against more than 100,000 intraperitoneal minimum lethal doses and more than 10 intracerebral minimum lethal doses of western equine encephalomyelitis virus but did not protect against either the eastern equine encephalomyelitis or St. Louis encephalitis virus es.

## COMMENT

The interest and the significance of the observations depend on the validity of the specific diagnosis. The seasonal incidence of this case of acute encephalitis, its symptoms and signs, the spinal fluid changes and the course of the disease are all consistent with what is known of the clinical picture of western equine encephalomyelitis in man. The question arises whether or not it is permissible to make an etiologic diagnosis of the disease based on the positive results of the immunologic tests. It is my opinion that such a diagnosis is entirely justified for the following reasons:

It will be agreed that the only possible explanations for the presence of strong specific protection against the western equine encephalomyelitis virus in the blood of this patient are either that the present illness was due to this virus or that he had suffered a previous inapparent infection with the virus which had left him with neutralizing antibodies against it unrelated to the present disease. The large amounts of antiviral substances present and their early appearance in the blood of the patient are in accord with the known facts of active infection of animals and man with both the eastern and the western variety of the equine encephalomyelitis virus. No extensive or systematic studies of the incidence of protective substances in the blood of random samples of the popula-

tions in nonepidemic areas or of asymptomatic contacts in epidemic areas such as have been made with reference to the St. Louis encephalitis and lymphocytic choriomeningitis viruses are as yet available for the equine encephalomyelitis virus. What information does exist on this point indicates that positive neutralization tests against the virus are found only in persons who have had the disease. Thus Gothergill<sup>1</sup> examined the serums of 58 familial contacts of patients with the disease and found them all negative. He concludes that "subclinical infection in man with the equine virus, except possibly under epidemic conditions must be very uncommon." In this connection I can state that I have examined the serums of 11 other patients with acute encephalitis of unknown etiology in the Chicago area together with the serums of 12 random normal controls for neutralizing antibodies to western equine encephalomyelitis and have found no evidence of protective antibodies in any instance. Two of these cases of encephalitis occurred in the summer of 1941. However, it appears that subclinical infections of this kind resulting in the presence of specific antibodies in the blood can occur under exceptional circumstances. Olitsky and Morgan<sup>2</sup> have reported strong neutralization against eastern equine encephalomyelitis in the blood of a laboratory worker who had been exposed to the virus for a period of six years without having symptoms of the disease develop. Five other workers also exposed to this virus showed no protection. It should be noted that the subject of this report was singularly free from any suspicion of exposure to the virus for many years prior to his illness.

In the light of the now established epidemiology of equine encephalomyelitis the implications of this case are twofold. It is possible that a reservoir of the virus has been established in the fauna of a large city and has

been transmitted by a local insect vector, in which case further urban outbreaks or epidemics may be anticipated. What seems more likely is that this patient was infected by an insect vector transported from an epidemic area in a common carrier (Pullman car).

## THE RENAISSANCE OF PROSTATECTOMY

WITH PARTICULAR REFERENCE TO MINIMAL  
HOSPITALIZATION, WITHOUT PRE-  
LIMINARY DRAINAGE

EDWIN DAVIS, MD

OMAHA

During the latter half of the past decade, certain definite and well recognized factors have resulted in changes almost revolutionary in character in the conception of prostatic surgery. These changes involve a complete remodeling of both professional and lay points of view with respect to operative indications, operative hazards, operative technic, functional results and, particularly, the necessity for preoperative drainage. I propose to enumerate and discuss briefly the causes of these fundamental changes and to explain and justify the apparent heresy which the title of this article implies.

On many occasions in the past I have expressed myself unequivocally with respect to the vital necessity of preprostatectomy drainage. Certainly until recently this has been the essence of successful prostatic surgery and the one factor of paramount importance responsible for the dramatic lowering of the prostatectomy mortality rate from above 40 per cent to below 3 per cent and for the conspicuous minimizing of the prostatectomy hazard to the end that the risk of this procedure in the aged and debilitated has come to compare favorably with that of appendectomy in the young and robust.

Exemplifying opinions expressed in the past, I cite the following: "As known by every one (but ignored by many), the answer to the uremia question is preoperative drainage, by retention catheter or via the suprapubic route, for days, weeks, or many months, insistently and inexorably carried out, for as long as may be necessary, regardless of urging to the contrary by patient, relatives or physician."<sup>1</sup> "The indispensability of preliminary drainage is too well recognized to require discussion."<sup>2</sup> "To the conservative and to those who have established conspicuously good records in prostatic surgery, the necessity for preoperative drainage is axiomatic. One might just as well seriously question the advisability of hemostasis." With but few exceptions, the patient in no need of preprostatectomy or preresection drainage is in no immediate urgent need of prostatic operation.<sup>3</sup>

Whereas Kretschmer,<sup>4</sup> Bumpus and Massey,<sup>5</sup> Emmett<sup>6</sup> and others interested in prostatic resection have advocated minimizing the preliminary drainage period, there are the enthusiastic supporters of this method who have advised caution. According to T M Davis,<sup>7</sup> "Adequate preliminary treatment is of paramount importance continued until the renal function has become stabilized," while G J Thompson,<sup>8</sup>

referring to patients with impaired renal function, has said "Let me reiterate that preliminary drainage is an absolute essential." The obvious conclusion is that the advisability of drainage depends on the condition of the individual patient rather than on the type of operation. As long ago as 1938, discussing transurethral resection and perineal prostatectomy, I expressed the opinion that "with only moderate amounts of residual urine and without impairment of renal function preliminary drainage may be fairly safely dispensed with," and, in fact, through the years, have occasionally followed this course. It has been my observation, however, that those persons who did not go through with the usual period of several days of preoperative elevation of temperature were most likely to experience a postoperative flare-up of pyelonephritis. Quoting further, "I much prefer to drain than be sorry, and follow this procedure with all but the conspicuously good risks." These statements continue true, and always will, as applied to patients with impaired renal function. Which brings to attention the chief item for emphasis, as well as the occasion for this paper, namely the fact that urologic surgeons, for reasons outlined hereafter, are now seeing a much larger percentage of patients who present a conspicuously good risk.

The factors responsible for this fundamental change in the attitude of the medical profession and of the public may be enumerated as follows:

- 1 The gradual recognition as fallacious of the tradition that prostatectomy is a hazardous ordeal
- 2 The development and popularizing of transurethral prostatic surgery
- 3 Popular lay magazine articles on genitourinary subjects
- 4 Syndicated newspaper articles by reputable medical columnists
- 5 Ethical "public enlightenment" programs, sponsored by medical societies
- 6 "Protect your health" magazine advertisements sponsored by life insurance companies
- 7 Persistent, blatant, radio advertisement by utterly unscrupulous charlatans
- 8 The introduction of the sulfonamide group of urinary tract antiseptics
- 9 What may be termed the modern tendency toward lay enlightenment

These influences combined, increasing public knowledge and the physician's confidence and decreasing the patient's dread, have been responsible for this fundamental and highly desirable change, which has made its spontaneous appearance, unsought and unplanned by the urologist. It has been realized that prostatectomy under proper conditions is not hazardous. Neither is it an ordeal. The dramatic lowering of the prostatectomy mortality rate, resulting from a better understanding of the problems relating to uremia, anesthesia, hemorrhage and infection, has had its influence but has probably been a less important factor than it should be. The popularizing of transurethral prostatic resection, resulting in wide publicity which emphasizes short term hospitalization and perhaps overemphasizes the innocence and simplicity of this procedure, has undoubtedly been an important influence in creating public confidence and willingness. Popular lay magazine writers, often inaccurate in their statements and painting unnecessarily lurid pictures, have aroused interest and curiosity, and have the syndicated newspaper columnists, the public programs sponsored by medical societies and the

meningitis advertisements. Each of these causes has had its influence, but the most potent factor of all in making "prostate" a household word and in causing this subject to be regarded as fit for general polite conversation has been the blatant program of fraudulent radio advertisement. It now appears that the deluge of malicious radio propaganda of this kind, designed to deceive and to demand has inadvertently rendered a genuine public service. As a certain eminent urologist referring to one notorious offender said "He has made us respectable." Present indications are that the use of sulfonamide derivatives has tended to lessen the frequency of postoperative flare-ups of pyelonephritis, thus increasing the confidence of the urologist in undertaking prostatic resection without preliminary drainage. And, finally, this change in the attitude of the public toward prostatic surgery is part of and in keeping with, the modern trend toward enlightenment and applies in other fields as well. People are now acutely vitamin conscious and sex hormone conscious. In fact the alphabet of vitamins seems to be less bewildering to the public than to the physician.

Prior to the recent days of enlightenment the midnight admission of the distressed and suffering old man with bladder visibly distended and urethra traumatized, bleeding and impassable was a frequent occurrence. I recall the necessity not many years ago in rather a small private urologic practice for emergency suprapubic cystostomy daily for eleven consecutive days. In contrast there was occasion for but one such operation during the twelve months following Jan. 1, 1940. While it is of course true that there are now many more efficiently operated small town hospitals, where such emergency operations are performed, the fundamental reason why comparatively few patients in desperate condition are now seen is the earlier recognition of prostatic obstruction by the intelligent physician and proper advice before the patient is desperately ill, coupled with the willingness of better informed patients to accept such advice. In former days the elderly patient was more or less uremic, often was disoriented and sometimes was delirious or even comatose. Under such conditions to omit preliminary drainage was almost equivalent to signing the death certificate. The patient faced many weeks or even months of hospitalization, with retention catheter or suprapubic drainage. There was no other way except to return the patient to his home burdened with the care of a suprapubic tube.

Today both physician and prospective patient, encouraged by favorable reports on the mortality and functional results of prostatectomy and by the glowing accounts of short term hospitalization offered by transurethral resection, have gradually become more inclined to the view that the hazard of operation is less than the hazard of delay. It has become recognized that to postpone until surgical intervention has become imperative is to increase materially the period of hospitalization, the cost of hospitalization and the risk. By the intelligent, prostatic resection is now regarded as a welcome means of relief rather than *le dernier ressort*.

The so-called conspicuously good risk may be defined as the man of an age for prostatic trouble who is apparently in good general health, with a good appetite, with definitely demonstrable prostatic hypertrophy, with a clearly defined history of recurrent attacks of urinary retention of unquestionable mechanical urinary obstructive symptoms, with residual urine not exceeding a few ounces, with approximately normal reaction to blood

nitrogen and phenolsulfonphthalein tests and without evidence of circulatory disturbance. I am not referring to what may be termed "prophylactic" prostatic operations. Obviously, under these circumstances there is nothing to be accomplished by ten days or two weeks of drainage by retention catheter accompanied by the usual flare-up of pyelonephritis unless one feels that there is advantage gained as a result of the immunity supposed to be conferred by "vaccination" of the urinary tract. I am prepared to express no opinion as to whether such advantage is fact or fancy. At any rate, I have felt justified in undertaking perineal prostatectomy without preliminary drainage on a small series of such patients recently under observation. In this series it seemed advisable also to attempt the prevention of postoperative pyelonephritis and the hastening of wound closure by the oral administration of sulfathiazole. Whether this drug is beneficial under these circumstances or whether the urologist is carried away by undue enthusiasm for the new remains for the future to determine. My present opinion, based on a small series only, is that

*Summary of Essential Data Obtained from the Case Histories and Hospital Records of Twenty-Four Consecutive 'Good Risks' Undergoing Perineal Resection Without Preliminary Drainage*

sulfathiazole given by mouth tends both to lessen the postprostatectomy elevation of temperature and to hasten the closure of the perineal incision. Of importance in this connection is the recent article by Young, Hill and Semans<sup>9</sup> describing decidedly better wound healing following plastic procedures for hypospadias with postoperative oral administration of this drug.

This preliminary report, including 24 case histories summarized in the accompanying table, is presented with the purpose of emphasizing (1) omission of preliminary drainage, (2) negligible postoperative elevation of temperature, (3) rapid closure of the perineal fistula and particularly (4) the almost incredibly short period of hospitalization, which compares favorably with that for transurethral resection. All the patients were in good general condition considering the average age. All were operated on via the perineal route under sacral block anesthesia with no sedative other than  $\frac{1}{4}$  gram (0.01 Gm.) of morphine sulfate. The operative technic, governed by the fundamental principles long since laid down by Hugh Young, has been described elsewhere<sup>2</sup> with emphasis on meticulous care in suture ligation of the bleeding points and on the obliteration by suture of the prostatic cavity, although complete plastic closure

9 Young, H. H., Hill, Justina H. and Semans, J. H. Use of Sulfathiazole Before and After Urologic Operations to Prevent or Combat Infection. *J. Urol.* 44: 714 (Nov.) 1940.

without drainage was carried out in no instance. Each patient received 0.5 Gm of sulfathiazole orally four times daily during the first ten postoperative days, while in half the series 5 Gm of sulfathiazole powder was deposited in the incision. Whether this drug employed locally after perineal prostatectomy tends to accelerate or to retard wound closure is debatable. My impression, based merely on observation of 12 patients who had and 12 who did not have the drug applied locally, is that antiseptic value is outweighed by tissue injury. The combined perineal drainage and hemostatic bag employed as a safety measure and slipped out in most instances after twenty-four hours appeared to interfere in no way with rapid wound healing. Drainage by urethral catheter was maintained for an average period of twelve days. Each of the patients made an uneventful recovery.

The patients came under observation in rapid succession. Except the first, the operations all were performed during a three month period. The point to be stressed is that during this time the admission of "conspicuously good risks" was decidedly the rule rather than the exception. Ten of the patients were consecutive. In fact, of 28 consecutive prostatectomy patients in my own series, 23 were in sufficiently good condition to permit operation without drainage. This recent "run" of good risks has been as amazing to me as I fear it may be incredible to the reader. Although such a high ratio of good risks may hardly be expected to be maintained indefinitely, there can be no question as to the fundamental character of the change in viewpoint which has taken place. The same tendency is apparent to a lesser degree in public wards. Of the 23 patients, 6 were public ward patients.

Chart 1, depicting 24 superimposed first week postoperative temperature curves, attests the innocence of perineal enucleation under the circumstances previously outlined. It is to be noted that only one of the curves exceeded the 101 F level. The average first week temperature curve, computed from the daily maximum temperature of each of the 24 patients, reached a peak of 99.9 F on the second day, as shown in the table and demonstrated graphically by chart 2. No preliminary

Chart 1—Superimposed first week temperature curves for 24 consecutive perineal prostatectomies on "good risks" performed without preliminary drainage. Each curve is plotted to show only the maximum daily elevation.

drainage was done in any case included in the table, although 1 patient had had interval catheterization prior to admission. It is to be observed that the average number of days of postoperative perineal urinary drainage (three) is by no means identical with the average time (seven days) which elapsed between the date of operation and the last day of perineal drainage. The apparent discrepancy between these two sets of figures is due to the fact that urinary saturation of the perineal

dressings during the average twelve day period of postoperative retention catheter drainage was decidedly the exception. In most instances such perineal urinary drainage as occurred was noted during the first or second postoperative day and also for a day or two after the removal of the retention catheter. The average total number of days of hospitalization exceeded the average period of postoperative hospitalization by one

Chart 2—Average maximum daily elevation of temperature following perineal prostatectomy on "good risks," based on the twenty-four consecutive superimposed curves shown in chart 1.

day only, since the patients were operated on the day after admission, after completion of the physical examination and functional tests. The average total hospitalization figure included the figure for 1 charity ward patient who had no postoperative perineal drainage whatever but who remained in the hospital for three postoperative weeks because of unexplained pain in the hip. The expression "total necessary hospitalization" is properly employed, since in a few instances the operation was postponed a day or two in order to suit the convenience of the surgical staff and since the patient himself occasionally elected to remain in the hospital after dismissal awaiting the arrival of relatives or for other reasons wholly unrelated to his physical condition. These extra unnecessary days have been excluded in figuring the total period of hospitalization. The average age was 67, the average residual urine (excluding that in 3 cases of complete retention) 3 ounces (85 cc) and the average size of the prostate 49 Gm. Although the number of days of postoperative perineal urinary drainage averaged three, 7 patients (30 per cent) had no perineal urinary drainage whatever. The total preoperative and postoperative hospitalization averaged sixteen days. These records have been checked by my colleague, Dr. C. A. Owens, who has made similar observations.

#### SUMMARY

By reason of recently increased public enlightenment and "prostate consciousness," the urologic surgeon now sees a much larger percentage of "conspicuously good risks," who permit safe prostatectomy without preliminary drainage.

The results obtained in a series of 24 consecutive cases in which the risk was particularly good indicate that the average total period of preoperative and postoperative hospitalization in the case of good risks may be reduced to a figure not exceeding sixteen days.

This exceedingly short average total hospitalization for perineal prostatectomy tends to nullify the chief argument of authorities advocating routine or indiscriminate transurethral resection rather than selective cases.

The opinion here expressed is not to be interpreted as blanket approval of prostatectomy without preliminary drainage, the necessity of which will also obtain in cases with impairment of renal function.

CUTANEOUS TEST WITH DIODRAST  
TO PREDICT ALLERGIC SYSTEMIC REACTIONS

FROM DIODRAST GIVEN INTRAVENOUSLY

HYMAN I. VATTERMANN, MD

AND

SAMUEL A. ROBINS, MD

BOSTON

Systemic reactions following the intravenous administration of diodrast for excretory pyelography are frequently disturbing and occasionally serious. Many of the symptoms such as sneezing, urticaria and wheezing resemble allergic manifestations so closely as to suggest that allergy to the diodrast may be a cause for the reactions. On one occasion after it was first determined that the intradermal injection of small amounts of diodrast was painless and caused no systemic reaction increasing concentrations of diodrast were injected into the skin of a patient who had recovered from a severe reaction to diodrast given intravenously; there was a strong positive cutaneous reaction when 0.05 cc of undiluted diodrast was injected intradermally. It was therefore decided to test in a similar manner all patients who were to receive diodrast intravenously for pyelography. The methods used and the results in a consecutive series of 404 patients are presented.

## METHODS

On arrival in the roentgen ray department for intravenous pyelography each patient was questioned regarding his family history and personal history relative to allergy. An intradermal cutaneous test was performed with 0.05 cc of undiluted diodrast injected into the skin of the forearm; an injection of the same amount of saline solution being used as a control, the diameter of the wheal and the area of erythema were measured after ten to fifteen minutes. Diodrast was then given intravenously in the usual manner for pyelography regardless of the result of the cutaneous test, symptoms were recorded as they occurred.

## RESULTS

The 404 patients were divided into two groups: 323 patients who had no general reaction to diodrast intravenously and 81 patients who did have a general reaction. Each group was then subdivided according to the severity of the local reaction to the cutaneous test. The local reaction to a cutaneous test resembled that occurring in foreign protein hypersensitivity in that it developed quickly after the injection, reached a maximum in ten to twenty minutes and faded quickly thereafter, disappearing completely. It consisted of an increasing wheal with a surrounding zone of erythema; there was pseudopod formation in the larger reactions. In 15 instances erythema did not appear although a wheal up to 10 mm occurred. Occasionally the wheal did not increase greatly and the erythema predominated in the reaction. The reaction to a cutaneous test was considered (1) negative when the wheal measured less than 8 mm and the erythema less than 10 mm, (2) slightly positive when the wheal measured 8 or 9 mm with no erythema or when the wheal measured less than 8 mm and the erythema 10 mm or more in diameter, (3) moderately positive when the wheal measured 10

to 15 mm and (4) strongly positive when the wheal measured more than 15 mm.

Of the 323 patients with no general reaction (table 1) 235 (72.8 per cent) had negative cutaneous reactions and 88 (27.2 per cent) positive. Of the 81 patients who did have a general reaction on the other hand, only 14 (17.2 per cent) had negative cutaneous reactions while 67 (82.8 per cent) had positive reactions. Of the 88 patients with positive cutaneous reactions and no general reaction (table 2), 75 (85.2 per cent) had only slightly positive cutaneous reactions and 13 (14.8 per cent) moderately positive reactions. No patient who had no general reaction had a strongly positive cutaneous reaction. Of the 67 patients who had both positive cutaneous reactions and general reactions, 43 (64.1 per cent) had slightly positive cutaneous reactions, 22 (32.7 per cent) had moderately positive cutaneous reactions and 2 (2.9 per cent) had strongly positive cutaneous reactions. It is evident that the patients with general reactions had a significantly higher percentage of positive cutaneous reactions than the patients who did not have general reactions. The sites of the cutaneous reactions in the patients with general reactions tended to be larger than those in the patients who did not have general reactions.

There were 249 patients with negative reactions to the cutaneous tests, of these 14 (5.6 per cent) had general reactions. One hundred and eighteen patients had slightly positive cutaneous reactions of whom 43 (36.4 per cent) had a general reaction. Thirty-five patients had moderately positive cutaneous reactions, of whom 22 (62.8 per cent) had a general reaction. There were 2 patients who had strongly positive cutaneous reactions, and both had general reactions. This would indicate that with a negative cutaneous reaction there is approximately one chance in twenty of having a general reaction, and as the cutaneous reaction becomes more strongly positive the chance of a general reaction developing progressively increases.

TABLE 1—Incidence of General Reactions and Positive Reactions to Cutaneous Tests

| General Reaction | Number of Patients | Reaction to Cutaneous Tests |          |          |          |
|------------------|--------------------|-----------------------------|----------|----------|----------|
|                  |                    | Negative                    |          | Positive |          |
|                  |                    | Number                      | Per Cent | Number   | Per Cent |
| All test         | 323                | 235                         | 72.8     | 88       | 27.2     |
| Pre test         | 81                 | 14                          | 17.2     | 67       | 82.8     |

There is no reliable method of determining whether or not a reaction is due to allergy. Therefore, any symptoms following the administration of diodrast was considered a general reaction. The most common reaction involved the gastrointestinal tract and consisted of nausea, with or without vomiting, it occurred in 57 (70.3 per cent) of the 81 patients with general reactions. The next most frequent manifestation of a reaction was urticaria varying from a few localized wheals to generalized urticaria, this occurred in 20 (24.6 per cent) of the patients with reactions. Nasal symptoms of stuffiness and sneezing occurred in 5 of the patients (6.1 per cent). Three patients (3.7 per cent) had "chest" symptoms: 1 with a wheal of 4 mm and erythema of 12 mm from the cutaneous test vomited, coughed and choked for three minutes; the symptoms beginning about one-half minute after the injection, a second, with a wheal of 8 mm and erythema of 11 mm as a result of the cutaneous test choked, coughed, became cyanotic and "brought up yellow fluid" for two to three minutes, the

From the Department of Bacteriology and Allergy and the Department of Radiology, Beth Israel Hospital; the Department of Medicine, Harvard Medical School; and the Department of Radiology, Tufts College Medical School.

third patient, with a reaction consisting of a wheal of 20 mm and erythema of 40 mm, had choking and cardiovascular collapse necessitating admission to the hospital. Seven patients (86 per cent) had miscellaneous symptoms, consisting of (1) pallor, (2) faintness during injection, (3) toxic encephalopathy, (4) pallor and sweating, (5) faintness after injection, (6) nausea, dizziness, increased pulse rate, chill and "shaking" and (7) vomiting, cyanosis, chills and "generalized discomfort" followed by a temperature of 101 F.

Comparison of the reactions to cutaneous tests with the severity of the general reaction revealed considerable variation. Some of the patients with negative or slightly positive cutaneous reaction had general reactions more severe than patients with moderately positive cutaneous reactions. Nevertheless, in general the more severe reactions occurred in those patients having more strongly positive cutaneous reactions. The 2 patients who had strongly positive cutaneous reactions had severe general reactions.

TABLE 2—Degree of Positive Reactions to Cutaneous Tests in Patients Without and With General Reactions

| General Reaction | Number of Patients | Reactions to Cutaneous Tests |          |                     |          |                   |          |
|------------------|--------------------|------------------------------|----------|---------------------|----------|-------------------|----------|
|                  |                    | Slightly Positive            |          | Moderately Positive |          | Strongly Positive |          |
|                  |                    | Number                       | Per Cent | Number              | Per Cent | Number            | Per Cent |
| Absent           | 88                 | 75                           | 85.2     | 13                  | 14.8     | 0                 | 0        |
| Present          | 67                 | 43                           | 64.1     | 22                  | 32.7     | 2                 | 2.9      |

TABLE 3—Family and Personal History of Allergy in Patients with Negative and Positive Reactions to Cutaneous Tests

| History of Allergy | Negative Reactions to Cutaneous Tests (249 Patients) |          | Positive Reactions to Cutaneous Tests (145 Patients) |          |
|--------------------|--|----------|--|----------|
|                    | Number   | Per Cent | Number   | Per Cent |
| Family             | 17   | 6.8      | 27   | 18.6     |
| Personal           | 9  | 3.6      | 31   | 21.3     |

The relation between the history of allergy and the result of the cutaneous test is presented in table 3. The patients with negative reactions to cutaneous tests had familial and personal histories of allergy similar to that in the general population, while among patients with positive reactions to cutaneous tests there was a considerably higher incidence of familial and personal history of allergy.

Each patient was questioned regarding previous contact with iodides. The information obtained could not be considered reliable, however, and no attempt was made to correlate this with the results of cutaneous tests or with the occurrence of general reactions.

COMMENT

The data of the present study have some bearing on the question as to whether or not reactions following intravenous injection of diodrast are due to allergy. Eighty-eight patients had no general reactions but did have positive cutaneous reactions, 75 of which were slightly positive and only 13 moderately positive. On the other hand, 14 patients, 34 per cent of the total number studied, had general reactions with negative reactions to cutaneous tests. This discrepancy is not unusual for allergic conditions. In other forms of allergy, e.g. hay fever, patients with clinical sensitivity may have negative reactions to cutaneous tests, and

other patients with positive cutaneous reactions may not have clinical sensitivity. The disturbances observed clinically during general reactions to diodrast, such as urticaria, nasal obstruction and sneezing, choking, wheezing and vasomotor collapse, are similar to the reactions occurring with "serum sickness." The character of the reaction to the cutaneous test with diodrast is also typical of allergy. Accordingly, allergy to diodrast must be considered a cause for the general reaction. This hypersensitivity, fortunately, must be very slight, since 0.05 cc of the undiluted solution was used in the intradermal tests, whereas in pollen sensitivity comparable intradermal reactions are frequently obtained with dilutions of pollen extract of 1:100,000 or more.

The mechanism of the hypersensitivity must await further study. In an attempt to demonstrate antibodies by inducing passive transfer, 0.1 cc of serum from a patient who had a strongly positive cutaneous reaction was injected intradermally into 2 normal subjects, no reaction occurred when the passive transfer sites were treated with 0.05 cc of diodrast. Since diodrast is a compound rather than a simple chemical substance, cutaneous tests should be done with its various components.

The value of cutaneous tests in predicting serious general reactions to diodrast is demonstrated by the results of this study. The most serious reaction to be expected is vasomotor collapse with death, probably the result of allergy. Other reactions, whether allergic or not, may be mildly or moderately distressing but otherwise are usually not of great importance. In this series, 77 general reactions were mild to moderate and were associated with negative to moderately positive cutaneous reactions.

There were 3 serious reactions. The first of these occurred in a 29 year old woman in whom intravenous pyelography was performed because of hematuria and dysuria. There was no family or personal history of allergy. She had not received diodrast previously. The reaction to a cutaneous test consisted of a wheal 5 by 6 mm, with no erythema. She was given 20 cc of diodrast intravenously, and, according to the nurse in attendance

Three minutes later, she became restless, moved all about the table and failed to respond to questions. The skin was warm and moist. The pulse was regular, of good quality and not rapid. In about ten minutes the patient became quieter. This was soon followed by another episode similar to that just described but less severe. At this time she started muttering irrationally. The skin was still warm and moist and the pulse good. After another ten minutes she quieted down. The skin became cold and pale. The pulse remained good. Epinephrine, 4 minims (0.25 cc), was given after fifteen minutes.

The patient was later observed by a consulting neurologist, who made the following note:

The occurrence of stupor with absent reflexes, followed by great irritability and twitching, with reflexes only partly returned, together with mutism and automatic and limited answers, indicates a widespread cortical, probably encephalopathic, response to a toxic influence.

There was a gradual return to normal in the next few days. This reaction is not typical of the allergic type, and a positive reaction to a cutaneous test could not, therefore, be expected.

Another serious reaction occurred in a 53 year old woman who was studied for pain in the right side. After receiving 20 cc of diodrast she became cyanotic

and dyspneic and collapsed. She was admitted to the ward where she was reported as being cyanotic with a barely perceptible pulse, clammy skin and a blood pressure of 90 systolic and 50 diastolic. She was placed in shock position and given epinephrine subcutaneously in 0.5 cc doses to maintain the blood pressure at 100 systolic and 60 diastolic. The patient gradually became warmer and more comfortable, the cyanosis giving way to erythema without wheals. There was a rise in temperature to 102.5 F which returned to normal the following morning. At this time she felt normal and stated she had previously felt as if she were dying. The reaction to a cutaneous test at this time was strongly positive consisting of a 20 mm wheal and 40 mm zone of erythema. The cutaneous test was repeated one week later and elicited a similar reaction.

The third severe reaction occurred in a 30 year old man with hay fever who was studied because of essential hypertension. A cutaneous test elicited a wheal 20 by 20 mm and a zone of erythema 35 by 30 mm but the control test with saline solution elicited a wheal 6 by 16 mm and a zone of erythema 30 by 30 mm. Because of the strongly positive cutaneous reactions the diodrast was injected slowly according to the attending nurse.

With the injection of a few cubic centimeters [7 cc] the patient became very flushed, the eyes reddened and became itchy, wheals came on the face and neck and the patient felt funny. Five-tenths cc of epinephrine was given subcutaneously, the wheals disappeared and he became pale and felt better.

Cutaneous tests were repeated some weeks later and he showed a wheal 20 by 20 mm and a zone of erythema 60 by 60 mm with both diodrast and saline solution. He was given 13 cc of saline solution intravenously with no reaction. A passive transfer study was done by injecting his serum into 2 recipients but no reaction occurred with diodrast or saline solution.

The 2 patients with severe general reactions typical of allergic reactions had the most strongly positive cutaneous reactions consisting of wheals, with pseudopods, measuring 20 mm, accompanied by large areas of erythema. Until more information is obtained it would seem prudent to perform cutaneous tests on all patients before diodrast is given intravenously and for those patients showing cutaneous reactions with wheals of 15 mm or more suitable precautions should be taken. The precautions should consist in having epinephrine available for instant use and the slow injection of the diodrast, stopping as soon as untoward symptoms develop. Since about 2 out of 3 patients with moderately to strongly positive reactions to cutaneous tests had general reactions, it may be of advantage to give such patients prophylactically one of the drugs, such as epinephrine or ephedrine, which counteracts allergic reactions.

#### CONCLUSIONS

1. One cause for the general reaction following intravenous injection of diodrast is allergy to diodrast.
2. The intradermal cutaneous test with 0.05 cc of diodrast usually elicits a positive reaction in a patient allergic to diodrast.
3. An intradermal cutaneous test with 0.05 cc of diodrast should be done on all patients before diodrast is injected intravenously.
4. If the reaction to a cutaneous test is strongly positive, with a wheal larger than 15 mm, a serious general reaction may be expected, and precautions should be taken.

## Clinical Notes, Suggestions and New Instruments

### ELIMINATION OF COLOR FROM VISUAL HEMOGLOBINOMETRY

DON H. DUFFIE, M.D., CENTRAL LAKE, MICH.

From their recent studies, involving hundreds of carefully controlled determinations by both physicians and technicians, Karr and Clark<sup>1</sup> conclude that "hemoglobin determinations, as they are done in many laboratories of accredited hospitals with accepted methods are so inaccurate that they are not only valueless but may well be detrimental to good medical practice." While not every one might have the blunt candor of these investigators there remains a widely sensed need for a better clinical method of hemoglobin determination than the methods now in use.

A method is here described that can be carried out complete in sixty seconds, including two or three readings, readings which in my practice seldom vary as much as 0.4 Gm (2 per cent) and which can be performed with a relatively inexpensive and reasonably fool-proof photometer that can be folded up and carried in the pocket.

The underlying principle of the method is that green light is absorbed by red such as the red of oxyhemoglobin in a solution. The more hemoglobin present the less green light will pass through the solution. If one has a constant source of light, together with means for measuring the amount of green light that does get through the hemoglobin content can be quickly and accurately measured. This is exactly the principle of the photoelectric colorimetric oxyhemoglobin method which was found by Karr and Clark to be the best of the methods tested by them.

Fig 1—Pocket size photometer for visual determination of hemoglobin by photoelectric methods without recourse to the photoelectric cell. The instrument is shown detached from its base as for use in an automobile. The inset at left shows the view through the eyepiece.

Notwithstanding a scholarly presentation by Kennedy<sup>2</sup> sixteen years ago and its independent application by Sunderman in an unpublished method,<sup>3</sup> it seems to have been quite overlooked that this excellent principle (heretofore inadvertently monopolized by the photoelectric colorimeter) can be most satisfactorily employed visually in any ordinary colorimeter without recourse to the photoelectric eye, yet without sacrifice of accuracy. The specifications for the green light filter, however, are considerably more exacting for visual than for photoelectric use.<sup>4</sup>

It is pertinent to note that the normal retina is appreciably more sensitive to minute differences in intensity of green light than it is to such differences of red, yellow or blue light. This

<sup>3</sup> Sunderman, F. W. Personal communication to the author.

<sup>4</sup> Theoretically the transmission of the filter should correspond closely with the absorption spectrum of oxyhemoglobin. A number 62 Wratten filter does well though it does not have very high total transmission. Kennedy used a number 74 filter.

means that green is the color of choice for precision in matching luminosity visually. As for the bogy of visual fatigue, I find distinctly less eyestrain in looking at greens than in peering at the pointer of an electrical device.

So narrow is the transmission band of the filter employed (number 74 and so on) that this same filter gives satisfactory readings in nearly all colorimetric tests, such as blood sugar and sulfonamide drug concentrations. In fact, number 74 is the filter specified by Sunderman and Pepper<sup>5</sup> in their serum concentration sulfathiazole method.

Fig. 2—Instrument and pipet assembly in case for carrying

For utilizing the visual method a simple pocket size photometer (figs 1 and 2) has been constructed. The instrument is similar in principle to the conventional microcolorimeter except that but one solution cup is used and no syringe or plungers are employed. Luminosity

of the controlled half of the visual field is governed by a sliding "optical wedge" of neutral gray interposed between that half field and the illuminant. Through the other half field is seen the cell of blood dilution, so that were it not for the green filter the field would appear half red and half gray.

Seen through the filter, however—and this is the whole point—the halves of the field are neither red nor gray but green. One has only to cause these contiguous areas of green to become of equal brightness by manipulation of the sliding gray wedge and then read the answer directly from the scale without taking the eye from the eyepiece, so several readings may be quickly made. To preclude "wishful" readings the scale is concealed by an occluder until it is desired to take a reading. The scale is divided into equal parts, either grams or percentage as preferred.

In designing the instrument, I took care to choose any parts liable to breakage or replacement so that they would be obtainable at trifling cost almost anywhere. The illuminant, for instance, is a small 6 volt bulb replaceable in nearly any dime store. The pipet is the ordinary 20 cu mm Sahli pipet, carried in stock by all surgical supply houses.<sup>6</sup> The solution cup is an ordinary 14 mm flat bottom vial, carefully selected for size. Contrary to theoretical apprehensions, in reality neither the meniscus of the free fluid surface nor lack of optical planity of the vial bottoms introduces any detectable error. The 6 volt bulb was chosen so that, while it is commonly lighted from a small transformer in the base of the instrument when 110 volt current is available, where this current is not available the detachable base and transformer may be left behind and the instrument lighted directly from the battery of an automobile through a wire from the dashboard or even from a standard lantern battery.

#### PROCEDURE

Precisely 20 cu mm of blood is blown from an accurately calibrated Sahli pipet<sup>2</sup> into approximately 2 cc of dilute alkali in the vial which serves as solution cup. Either 0.1 per cent sodium carbonate or 0.4 per cent ammonium hydroxide (4 cc of 28 per cent ammonium hydroxide to the liter of distilled

water) may be used. The quantity of blood is the only factor requiring precision measurement. Unlike the plunger type of colorimeter, this instrument does not require an exact amount of diluent.

If ammonium hydroxide solution is used, the vial may be slipped into place and the reading made at once if desired, with no waiting for an electric cell to warm up or for color to develop. Corked vials may be collected when one is making rounds, for reading on return to the laboratory.

#### First Attempts of Inexperienced Children

| Reading of Child Aged 14, Gm | Readings of Child Aged 12, Gm |

I have used the method here described in my practice for nearly two years with utmost satisfaction.<sup>7</sup>

To see what could be done by utterly inexperienced persons who did not know too much, I invited 2 school children aged 12 and 14 years who had never seen a colorimeter to make readings. The results shown in the accompanying table are their first (blind) readings after one minute's instruction with no practice allowed, all readings are given.

#### TYPHOID PULMONARY ABSCESS

T. HAYNES HARVILL, M.D., DALLAS, TEXAS

Pulmonary abscess complicating typhoid is not unusual, such an abscess of proved typhoid etiology is more rare. The first available report was that of Mussey to the Anatomy Society of Paris in 1838.<sup>1</sup> Postmortem examination on a patient with typhoid showed multiple metastatic pulmonary abscesses.

Fig. 1—Course of hospitalization. Temperatures are daily averages of rectal temperatures. Solid blocks indicate positive cultures, stippled blocks negative cultures, arrows indicate chest roentgenograms, X's hemoptyses.

Griesinger<sup>2</sup> reported 7 cases of pulmonary gangrene among 118 patients with typhoid coming to necropsy, and von Liebermeister<sup>3</sup> cited 14 cases of pulmonary gangrene found on necropsy examination of 230 patients with typhoid.

7. Sometimes physicians or technicians are a bit too smug or sure to give even a few moments attention to mastering details of a new method, details of which, however, may be important for accuracy.

6. For any close approach to absolute values the pipet should be calibrated by the United States Bureau of Standards. Accuracy of pipets as purchased is not high, one large manufacturer claiming no closer tolerance than 5 per cent. H. L. Alt of Northwestern University Medical School, said in a personal communication that the Hellige has been found most accurate of the pipets tested by him.

Pulmonary abscess of proved typhoid etiology must of necessity date from the recognition of the stained typhoid bacillus by Eberth in 1880 and of its cultural and differential bacteriologic characteristics by Gaffky in 1884 and Escherich in 1885. Since that period of isolation of the causative organism in 7 cases of pulmonary abscess complicating typhoid and 1 case of such abscess complicating a paratyphoid infection have been reported.<sup>1</sup>

Three of these communications present bacteriologic evidence substantiating the specific typhoid etiology of the complication. Basch<sup>4</sup> reported that a patient with typhoid on the fifteenth day of the illness showed signs and symptoms of lobar consolidation in the right lung. Examination of the sputum revealed a pure culture of *Eberthella typhosa* for a period of two months. Examination for the tubercle bacilli and pneumococci gave negative results. Roentgenograms of the chest showed an abscess at the angle of the right scapula. The outcome was not mentioned.

Chinn<sup>5</sup> presented a patient who for a year had periodic attacks of cough and catarrh lasting from fifteen to twenty days with good health in the intervening time except for continuous pain in the left side of the chest. Immediately prior to examination there was moderate low grade fever

tioned. Roentgenograms of the chest showed a pulmonary abscess with fluid level. Six days later a paroxysm of coughing was productive of foul blood-tinged sputum in which there were numerous paratyphoid bacilli. Roentgenograms nine weeks later showed a small infiltration the size of a quarter (24 mm).

To these 3 reports of typhoid and paratyphoid pulmonary abscess a fourth is here added.

#### REPORT OF CASE

G. R., a white man aged 36, was admitted to the University Hospital Feb. 3, 1938. Thirty-nine days previously he experienced a chill of fifteen minutes' duration followed by a sensation of fever. These chills recurred four or five times a week at no regular intervals and there was daily fever. The week prior to admission there was a morning cough productive of what was thought to be postnasal drip. On several occasions this material had been bloody, but the evaluation of this symptom was complicated by the presence of concurrent epistaxis.

On examination the patient was emaciated and apathetic and was acutely ill. The rectal temperature was 102.8 F, the pulse rate 104, the respiratory rate 18 and the blood pressure 110

Fig. 2—Appearance of the chest on admission to the hospital, negative.

Fig. 3—Appearance of the chest on the forty-second hospital day. There is a large pulmonary abscess at the level of the third left anterior interspace and the fourth rib.

Fig. 4—Appearance of the chest at the time of discharge, persistent pneumatocele at the level of the third left anterior interspace.

epigastric pain and vomiting. Roentgen examination of the chest showed an opacity at the base of the left lung interpreted as free fluid with pulmonary excavation and a bronchopleural fistula. Postural drainage yielded pus of the same character as that obtained by thoracentesis, both of which showed a pure culture of *Eberthella typhosa*. It was the author's opinion that the patient had an ambulatory form of typhoid with abscess localization in a locus minoris resistentiae.

Thumm<sup>7</sup> examined a patient whose history revealed that four weeks prior to examination there had been chills, fever and malaise which subsided but which was followed three weeks later by recurrence of the symptoms with the addition of pain in the anterior part of the left side of the chest. An exudate obtained from the left pleural space yielded a pure culture of *Eberthella paratyphosa*, its subclassification not men-

tioned. A blood clot was present in the left side of the nose. Breath was foul and there was profuse mucopurulent material on the posterior pharynx. At the apex of the left lung breath sounds were slightly diminished in intensity and occasional post-tussive rales were heard. The spleen was palpable at the rib margin and descended 3 cm on deep inspiration, the edge being sharp and nontender. The liver edge was just palpable in the midclavicular line on deep inspiration. The remainder of the physical examination gave negative results.

Leukocytes numbered 6000 per cubic millimeter with 80 per cent polymorphonuclear neutrophils. There was 1 plus albuminuria with occasional red and white blood cells in the urinary sediment. Bacteriologic examination isolated *Eberthella typhosa* from the blood, stool and sputum on numerous occasions as shown in figure 1.

The chest was examined with roentgen rays on seven different occasions. The initial film at the time of admission was negative (fig. 2). Roentgenograms on the thirty-fifth hospital day following a hemoptysis and again one week later (fig. 3) showed a pulmonary abscess in the midaxillary portion of the upper lobe of the left lung. Subsequent roentgen examinations showed progressive clearing of this abscess (fig. 4).

The course of the illness is outlined in the accompanying chart (fig. 1). Each recorded level of temperature is a daily average of six rectal determinations; there being wide fluctuations not apparent on the chart for this reason. The tempera-

ture subsided gradually and became normal during the latter part of the fourth hospital week. This was followed by a recrudescence of the febrile course during which sulfamidide was administered. On the twenty-first and twenty-second hospital days (sixty-first and sixty-second days of the illness) there was pain in the left upper anterior part of the chest and blood streaked sputum. Physical examination at that time gave negative results. Except for slight discomfort in the left side of the chest there were no other pulmonary symptoms until eleven days later, at which time there was a small hemoptysis, culture of which yielded *E. typhosa*. On this occasion, roentgenograms of the chest showed a pulmonary abscess. The blood culture was positive at this time. Following this there was a slight cough with small amounts of sputum, cultures of which were positive for the typhoid bacillus ten days later and negative thereafter. With the advent of negative sputum and blood cultures the temperature subsided and the patient proceeded to an uneventful recovery. At the time of discharge roentgenograms of the chest showed, at the site of the former abscess, a persistent pneumatocele with minimal surrounding inflammatory infiltration (fig 4). A follow-up letter from the patient thirteen months later informed me that for two weeks after discharge there was slight pain in the left side of the chest but no subsequent symptoms. At that time he was in excellent health. No further roentgenograms were available.

## COMMENT

It is realized that the positive sputum cultures were obtained at a time when the bacteremia was still present. However, the second positive sputum contained no apparent blood. The positive sputum cultures and the spontaneous healing of the abscess concurrent with the subsidence of the generalized disease lead one to attribute the pulmonary complication to typhoid etiology rather than to a nonspecific process. It is entirely possible that the abscess may have resulted from a septic embolus.

In the years 1935-1940 at the University Hospital there have been 272 other cases of pulmonary abscess. None of these occurred in typhoid patients. During the same period there were 34 cases of typhoid and 12 cases of paratyphoid fever, no other of which was complicated by pulmonary abscess.

1719 Pacific Avenue

## URETERAL OBSTRUCTION FOLLOWING THE USE OF SULFADIAZINE

SAMUEL L. RAINES, M.D., MEMPHIS, TENN.

Following the use of sulfapyridine and sulfathiazole there have been numerous reports in the literature of renal complications and ureteral obstruction. The case I am reporting is the first of this type to occur after the use of sulfadiazine. In symptomatology it differs little from ureteral obstruction following the administration of other drugs, but there are several points of practical importance that will be of interest.

According to earlier reports, sulfadiazine was more potent, less toxic and less likely to precipitate in the urine than any of the other sulfonamide drugs. Norman Plummer<sup>1</sup> of Bellevue Hospital, Finland<sup>2</sup> of Boston, Long<sup>3</sup> of Johns Hopkins and Flippin and his associates<sup>4</sup> have used sulfadiazine extensively. When all their cases are grouped it is found that they report renal complications in only 3 to 4 per cent of about 1,500 patients treated and only 1 instance in which suppression of the urine or precipitation followed administration of this newer drug. It has been my misfortune to see several patients recently in whom it obviously caused damage and in 1 instance death.

## REPORT OF CASE

W. D., a white man aged 69, was in good health until a few months before admission. Following the extraction of some teeth he began to lose his appetite, which was followed by a loss of weight and vigor. Several weeks later he began having a fever of moderate degree and a cough with a feeling of congestion in his lungs. Urinary examinations disclosed no abnormality, and he was admitted to the Baptist Hospital on August 29 under the care of Dr. W. C. Colbert.

His temperature on admission was 99.3 F., his pulse rate 100 and his respiratory rate 26 a minute. The urinalysis was negative. The white blood cell count was 19,560 with 92 per cent polymorphonuclear leukocytes, 3,700,000 red blood cells and 62 per cent hemoglobin. He had lost about 30 pounds (13.6 Kg.). The physical examination suggested a lung abscess, and this diagnosis was confirmed by a roentgen examination. Thirty grams (2 Gm.) of sulfadiazine was given initially, followed by 15 grains (1 Gm.) every four hours. On the second day the temperature became normal and remained so. On the third day after admission the patient experienced discomfort in the lower part of the abdomen with a feeling of indigestion and gaseous distention. He was given an enema and later gastric lavage, followed by sedatives which gave him partial relief. That evening at 6 o'clock, seventy-two hours after beginning the sulfadiazine, he passed a little blood-tinged urine and then stopped voiding. The sulfadiazine was discontinued at once and for two days he was treated symptomatically. During these two days his temperature, pulse and blood pressure remained within normal limits, although he became drowsy and sluggish, and the urinary output remained scanty.

A cystoscopic examination was decided on and on this examination there were found crystals and small concretions on the floor of the bladder. Both ureteral orifices were found bulging and apparently tightly impacted with some substance. I was unable to get a catheter up the right ureter. A number 5 catheter was inserted into the left ureter and met a crunching, crackling resistance in the lower third. After the catheter was inserted several cubic centimeters of cloudy, bloody urine, alkaline in reaction, was obtained. The urine continued to drip a little during the remainder of the manipulation. Thinking that the excretion from one kidney would give the patient partial relief and wishing to spare him the trauma of further forcible manipulations in attempting to open the right ureter, we returned the patient to his room. This catheter drained only 2 or 3 ounces (60 or 90 cc.) a day and he voided about the same amount for two more days. During this time his temperature, pulse, respiratory rate and blood pressure remained within normal limits.

On September 5, four days after the onset of anuria, under spinal anesthesia, another examination of the bladder was done. After considerable forcible manipulation with a heavy blunt-nosed number 7 catheter, a number 5 catheter was finally pushed up through the obstructing material in the lower third of the right ureter. About ½ ounce (15 cc.) of cloudy urine was secured through this catheter. The catheters in both ureters were irrigated and left in place, draining nicely. We continued to give dextrose intravenously, which had been started at the onset of anuria, and finally used some Fischer's solution to aid in stimulating urinary excretion. The output continued scanty and the patient became unconscious.

On the second day after the cystoscopic examination, or six days after the onset of partial anuria, the patient's temperature rose to 103 F. The respiratory rate increased and he began to cough. Dr. Colbert concluded that the infectious process in the lung had become active again. The blood pressure was 105 systolic and 50 diastolic, and the white blood cell count was 20,100 with 94 per cent polymorphonuclear leukocytes. The nonprotein nitrogen in the blood was 86 mg. per 100 cubic centimeters of blood. This was surprisingly low after six days of anuria. The next day, or one week after the beginning of anuria, the kidneys began to excrete urine. This encouraged us somewhat, although the patient remained critically ill and had a daily rise of temperature and rapid respiratory rate. Dr. Colbert aspirated the fluid of the chest and secured about 75 cc. of serous fluid.

pink from the azosulfamide that had been given intramuscularly the night before. The urinary output continued satisfactory and after two more days nine days after the beginning of anuria the temperature went below 100 F and remained there. The pulse became stabilized at about 90 a minute and the respiratory rate at 18. Improvement continued for another twenty-four hours and on the tenth day after the onset of anuria the temperature was 99 F, the pulse rate 70, the respiratory rate 20 and the nonprotein nitrogen 29 mg per hundred cubic centimeters of blood. The patient's general condition seemed greatly improved although he was stuporous and completely unconscious. Since he had received only dextrose intravenously for nourishment for eight days an attempt was now made to feed him. Fluids principally proteins were given by the Levin tube, and at 8 o'clock that night a blood transfusion was given. At midnight he became cyanotic and his muscles began to twitch. His condition grew rapidly worse. The next morning at about 10 o'clock he died.

#### COMMENT

There are several features of this case that seem worthy of discussion. At the onset his pain was in the abdomen and we did not realize that the ureters were completely blocked. A patient who has had sulfadiazine or any other sulfonamide preparation and who has abdominal pain a decrease in the urinary output and hematuria should have a cystoscopic examination performed at once to establish the patency of the ureters. One should not wait for the pain to radiate to the flank and kidney region as it may never do so and valuable time may be lost. Roentgen examinations do not help in the diagnosis, since apparently these concretions do not cast opaque shadows even when present in quantity.

Another patient was seen in the Methodist Hospital by Dr Hubert Turley. The onset was somewhat the same as in our case. Dr Turley promptly inserted catheters, thus relieving back pressure, and obtained a rapid response, and the patient lived. We had no trouble in getting up into the left ureter of our patient, but after we had waited four days it took a spinal anesthetic and forcible pressure to open the right ureter. The obstruction on the right side extended about 2 or 3 inches up, and we made our best progress by alternating the use of a blunt-nosed number 7 catheter and a sharp pointed number 5 catheter with a steel stilet in place.

Another point of discussion is whether or not to give alkalis with the sulfonamide type of drug. In the earlier days of sulfanilamide some men advocated alkalis to enable the patient to tolerate the drug better and avoid vomiting. For that purpose alkalis seem of little value. Possibly it would be of some help in the prevention of acetyl sulfadiazine precipitation. Theoretically, and actually, this drug is more soluble in an alkaline solution. If the urine was alkaline to a pH of 9.6 to 9.7, it would be in the same range as a 10 per cent solution of sodium sulfadiazine. The acetyl form at this same pH would be exceedingly soluble. Dr Burbidge<sup>5</sup> states that "the solubility of acetyl sulfadiazine in urine buffered at a pH of 6.9 is equal to 85 mg per hundred cubic centimeters. From these figures we can conclude that, the more alkaline the urine, the more soluble the acetyl form of sulfadiazine, and therefore the less chance there is of urinary calculi formation." Spence<sup>6</sup> of Dallas, Texas, in reporting on sulfapyridine deposition in the urinary tract, quoted Tsao in China, who had 4 instances of concretion in an alkaline urine. Schwartz and his associates<sup>7</sup> reported that the use of alkalis in the amount equal to the dosage of the drug prevents the occurrence of crystalluria in patients who are receiving sulfathiazole and sulfadiazine. Gershon Thompson<sup>8</sup> of the Mayo Clinic says that in the case of sulfadiazine this is open to considerable question. Grayson Carroll<sup>1</sup> of St. Louis believes that alkalis are not of any value

in this connection and states that heat is the only thing that will dissolve them. It may have been accidental, but I observed that the urine did not begin to excrete during this period of anuria until the temperature had risen to 103 F. On this basis I should consider the use of fever therapy, diathermy or other methods of raising the internal heat level in similar cases.

The consultants raised the question of when to remove the ureteral catheters, pointing out that the mere presence of these catheters sometimes causes a reflex anuria. We were afraid to take them out too quickly for fear there would be sufficient impinged material remaining to block the ureters again. It seemed to me that after the urine began to flow rapidly and was alkalinized we could certainly have removed them safely.

Dr Colbert mentioned that children who are deficient in vitamins and in a poor state of nutrition are much more likely to have ureteral and renal complications following administration of sulfonamides than are others. This might hold true for adults, as in our case. We had a patient who had been in poor general health, was undernourished and probably had a lowered resistance before the drug was given. Dr Spence<sup>6</sup> mentions dehydration as a predisposing cause of these complications.

There are certain precautions that one can and should take routinely for early detection and recognition of this complication. A daily urinalysis is of great importance. If red blood cells are present, the drug should be stopped immediately. The nonprotein nitrogen in the blood can be estimated or the concentration of the drug in the blood measured as a guide for further treatment. Of even greater importance is the measuring of the daily output of urine. Dr E. K. Marshall<sup>1</sup> of Johns Hopkins University stressed the fact that many cases of hematuria and anuria have occurred in patients owing to neglect in maintaining the urinary volume and allowing it to decrease to as little as 500 cc a day or less. Thompson<sup>8</sup> and many others have stressed the fact that the daily urinary volume of these patients should be between 1,200 and 1,500 cc. Physicians have frequently been warned to make regular blood counts on patients taking sulfonamide compounds, but it would seem more essential to examine the urine for volume, red blood cells, specific gravity and albumin.

In response to an inquiry I have an interesting observation from Dr Leon Herman<sup>1</sup> of Philadelphia. "At the moment we have a most fascinating case here in the person of a doctor who has passed seventeen stones and has had prolonged hematuria, notwithstanding the fact that the last dose of sulfathiazole was in April. Strange to say, his blood continues to show a considerable amount of the drug." Of course this was with the use of sulfathiazole, but the same thing might conceivably occur with any sulfonamide preparation.

The cause of death was probably toxemia, since the urinary output was normal and the nonprotein nitrogen was only 29 mg per hundred cubic centimeters of blood. This would apparently exclude the urinary tract as the cause of death. However, without anuria and other renal complications, this patient would most likely have recovered from the pulmonary infection.

#### CONCLUSIONS

- 1 Sulfadiazine, although widely thought to be less dangerous than sulfathiazole, has been shown in at least 2 instances to cause dangerous renal complications.

- 2 Any patient receiving a sulfonamide drug who has pain in the lower part of the abdomen, diminution of urinary output and hematuria should certainly be suspected of having ureteral obstruction from precipitation. Immediate ureteral catheterization should be done.

- 3 Heat seems to be the principal aid in dissolving these crystals.

- 4 Any patient receiving the drug should have daily urinary examinations done.

- 5 Dehydration and malnutrition seem to predispose to urinary complications.

- 6 I do not question the therapeutic effectiveness of sulfadiazine but wish to call attention to complications that many have thought would hardly occur with this drug.

## ELECTROCUTION BY HOME TREATMENT DEVICE

RICHARD KOVACS, M.D., NEW YORK

"Electric Shock Kills Pastor" was the caption of a story in the New York Times of Feb 20, 1942. The Rev L G W of a Long Island Universalist Church was found dead in his room the night before. According to information obtained from the office of the chief medical examiner of Nassau County he was found lying on the floor of his bedroom, fully clothed except for his coat. A metal electrode was on the back of his neck, slipped under the collar and held in place with a scarf. A wire led from the electrode to the radiator and was wired to the radiator. A rheostat was plugged in a wall socket, the handle of a "violet ray" machine was on the deceased's chest and a circular hollow piece of metal was in his left hand, as illustrated in the accompanying sketch.

The pastor had complained of pain in the back of his neck for some time, but neither the landlady nor an osteopath who had given him a few treatments could supply any other facts.

Autopsy performed by the medical examiner showed acute congestion of the brain, liver and kidneys, follicular hyperplasia of the spleen and first degree burns of the left hand, forearm, back of the neck and anterior portion of the chest.

To reconstruct the sequence of events, the deceased undoubtedly attempted to treat his back pain with the violet ray contraption and, in the mistaken belief that "grounding" would

Electrocution from violet ray apparatus

increase the strength of the current and thus the efficiency of treatment, after plugging in the handle of the violet ray outfit, rigged the connection between the radiator and the metal plate on the back of his neck. No better way could have been devised to conduct the alternating current from the return ground through the cardiac area. Hence, as soon as the current flow was started it caused local burns at the point of entry and at the same time cardiac fibrillation and instantaneous death, without giving the victim any chance to disengage himself from the fatal circuit. Cardiac fibrillation is the usual cause of death in electrocution, because of its very short duration before death ensues there occur usually no characteristic pathologic changes in the heart itself. The acute congestion in the vital organs is a secondary effect of death by electricity as in asphyxiation.

The object lesson of this tragic happening is obvious. Any sort of self treatment by electric devices—home made or procured from unscrupulous manufacturers or their sales agents—may cause death by electrocution when applied by inexperienced and unskilled lay persons.

2 East Eighty-Eighth Street

**Doing a Great Favor**—When the faculty of a medical school realizes that a student is indifferent and lacks zeal and that that student is liable to become a tragic figure in the profession, they are doing the public, as well as the profession, a great favor by asking him to withdraw and enter some other field of activity—Sproule, Ralph P. A Doctor Speaks to Students, *Marquette M Rev* 51 (Nov) 1940

## Council on Pharmacy and Chemistry

## REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS  
AUSTIN E. SMITH, M.D., Acting Secretary

## TEN PER CENT SOLUTIONS OF SODIUM MORRHUATE OMITTED FROM N N R

For some time the Council has recognized the use of solutions of sodium morrhuate as a sclerosing agent for the injection treatment of varicose veins, and both 5 per cent and 10 per cent solutions in combination with a local anesthetic, marketed in ampuls and rubber stoppered vials by several pharmaceutical concerns, have been accepted for inclusion in New and Non official Remedies.

Late in 1940 a physician brought to the attention of the Council office the serious results which had occurred in 5 cases following the injection of a Council accepted brand of the 10 per cent solution for treatment of varicose veins in the lower extremities and submitted for examination samples of the product that had been used in these cases. The physician explained that injection of a 5 per cent solution from previous orders had caused no difficulty in similarly treated patients. With the last batch purchased, however, injection of the 10 per cent solution in 5 cases produced fatal results in 2 and unfavorable symptoms in the other 3. One of the deaths occurred a few days after incision for a severe suppurative phlebitis which followed an injection of 2 cc of the solution into the internal saphenous vein some distance above a suppurating ulcer. The patient was previously twice injected for infected suppurative veins. Death (which occurred after the third injection) was attributed to thrombophlebitis and septic pneumonia from small pulmonary septic thrombi. The other death occurred in a robust man of about 50 (who had had an injection of the 5 per cent solution some months before) within twenty-five minutes after injection of 2 cc of the solution into the internal saphenous vein. About four minutes after the injection the patient became dizzy and short of breath. After eight minutes he became comatose and extremely cyanotic. Death was attributed to a large pulmonary embolism. In neither of the two fatalities was permission obtained for an autopsy to establish the cause of death. In the 3 nonfatal cases severe acute localized phlebitis developed with redness and extreme tenderness at the site of injection of the solution. In 2 of these recovery was uneventful, in the third case it was necessary to open the vein and express the apparently sterile clot. The quantity of the 10 per cent solution of sodium morrhuate which was injected in the 3 cases in which recovery occurred was not indicated. The physician expressed the belief that, in view of the previously satisfactory use of the 5 per cent solution, the accidents were due to the stronger solution. That death from pulmonary embolism may occur following sclerosing therapy for varicose veins, in the presence of acute or subacute phlebitis, was recently pointed out by Nunn and Harrison<sup>1</sup> in a brief review of the literature.

Examination of the submitted samples of the solution by the A M A Chemical Laboratory revealed that they conformed to the N N R standards of composition and supported the manufacturer's observation that the accidents were not attributable to chemical or bacteriologic defects in the 10 per cent solution. Accordingly, the Council's referee questioned whether there is need for the 10 per cent solution of sodium morrhuate and whether there is evidence to indicate that it will confer any benefit which a 5 per cent solution cannot accomplish. In the absence of published definite evidence concerning the value or safety of the 10 per cent solution, the firm's offer to conduct a survey of the opinions of authorities on sclerosing therapy of varicose veins, to afford an answer to the referee's question, was accepted. The results of this survey have been

<sup>1</sup> Nunn, L. L. and Harrison, J. H. Death from Pulmonary Embolism Following the Injection of Varicose Veins. *J A M A* 117: 347 (Aug 2) 1941.

been submitted to and considered by the Council. It was the consensus of the authorities who have had experience with both the 5 per cent and 10 per cent concentrations of sodium morrhuate solution that the 10 per cent solution (which is used relatively infrequently) may be potentially more toxic than the 5 per cent solution and that when the latter is inadequate additional surgical measures should be instituted rather than the employment of a stronger solution.

In its consideration of the 10 per cent solution attention was also directed to reports which have been published concerning reactions following injection of the 5 per cent solution for varicose veins. Praver and Becker<sup>2</sup> have reported untoward reactions in the form of cutaneous eruptions in 7 of 176 patients who received a total of seven hundred and eighty-three injections of this solution. Most of the reactions consisted of grouped urticarial wheals at sites of previous injection and were attributed to sensitization with the sodium morrhuate. The amount of protein present was considered too small to account for this but the authors suggested that sodium morrhuate may act as a haptene. Lewis<sup>3</sup> observed that mild localized urticarial rashes are fairly common and reported a case of temporary collapse following the injection of this solution (after a previous similar injection) which he attributed to constitutional anaphylaxis through the development of foreign protein sensitivity. Dale<sup>4</sup> has reported the sudden development of vertigo, faintness, bradycardia resembling heart block and cyanosis of the extremities without manifestation of anaphylactic phenomena following an injection of the 5 per cent solution in a case in which similar injections had previously been made repeatedly. He questioned the validity of sensitization as the explanation for Lewis's case on the ground that the symptoms were not anaphylactic in nature and that there was no period of cessation of treatment during which the patient could have become sensitized. He considered the reaction as specific and attributed it to idiosyncrasy.

McCastor and his associates reported a similar case of collapse following a single injection of the 5 per cent solution in a case in which a similar injection without reaction had been made five days previously. There was a previous history of urticaria. In a recent symposium on varicose veins at the Mayo Clinic, Smith, Weisman, McCallig, Heyerdale and others<sup>6</sup> indicated the successful use of the 5 per cent solution in the patients treated by their group. The use of a preliminary test dose is recommended with observation for twenty-four hours before proceeding with treatment to avoid possible untoward reactions.

These reports not only tend to throw some light on the nature of the reactions which have occurred with sodium morrhuate but indicate the need for reasonable caution in its use as a sclerosing agent. After due consideration of the available information the Council voted to omit all accepted brands of the 10 per cent solution of sodium morrhuate because of its questionable utility and greater toxic potentialities over the 5 per cent solution and because serious accidents have followed the use of the stronger solution for the injection treatment of varicose veins. The Council authorized a revision of N N R to include a recommendation for the use of a preliminary test dose as a precaution against untoward reactions with 5 per cent solutions. The manufacturers whose Council accepted solutions of sodium morrhuate were affected by this action were accordingly informed, and all concerned have agreed to withdraw the 10 per cent solution from the market in view of its greater potential danger.

## DEXTROSE SOLUTIONS WITH BUFFERS OMITTED FROM N N R

Sterile solutions of dextrose-U S P 50 per cent w/v in combination with buffer substances such as sodium and potassium phosphate or sodium citrate (or packaged with a separate ampul of buffer solution for mixing) to render them less acid have been included in New and Nonofficial Remedies for several years. The Council accepted preparations of this type have been marketed by six different pharmaceutical manufacturers in ampuls containing amounts up to 100 cc for intravenous injection. Three of these concerns also market similar solutions of dextrose which are not buffered or packaged with a buffer solution. In view of this and the well established successful use of unbuffered sterile solutions of dextrose intravenously in both small and large quantities the manufacturers of the accepted buffered preparations were requested to furnish evidence to justify the need or value for the addition of buffers to solutions of dextrose; they were advised that unless they could offer such evidence their buffered solutions of dextrose would not be recommended for reacceptance.

The replies received from the firms that attempted to support their buffered dextrose solutions advanced as the principal arguments the claim that buffers are added to avoid excessive acidity and that there is a demand for the buffered preparations. One concern indicated that the buffers serve to stabilize the solution and another that they render the solution isotonic with the blood. The other firms either offered no comments or indicated that they had no evidence to support the inclusion of buffers in solutions of dextrose. None of the concerns gave any reason why it was necessary to supply both buffered and unbuffered solutions of dextrose beyond the argument that they are in demand. The arguments which were advanced were answered by pointing out that the A M A Chemical Laboratory has expressed the opinion (with concurrence of the Council) that the degree of acidity developed in unbuffered dextrose solutions is not clinically significant; that unbuffered solutions may remain stable over a period of three years and that buffers are added for the purpose of altering the  $pH$  of the solution rather than for any direct influence on the toxicity (osmotic pressure) of the solution. Recently in its consideration of a further brand of dextrose solution which was buffered the Council indicated that when a buffer is needed for intravenous administration as in disturbances of acid-base balance it should be given separately in the form of Lactate-Ringer's solution or sodium  $r$ -lactate one-sixth molar (187 per cent w/v).

It is furthermore not altogether clear whether the dextrose solutions are buffered primarily for the purpose of stabilization or to render the  $pH$  of the solutions approximately the same as that of the blood. In either case the need for buffers in solutions administered to supply fluid or physiologic salts or carbohydrate is not supported by past experience. The buffering mechanism of the blood itself is apparently adequate to take care of relatively large volumes of moderately acid or alkaline solutions which are commonly administered intravenously. The use of buffers to control the  $pH$  of solutions should be clearly distinguished from the practice of adjusting the concentration of ingredients in solutions to make them isotonic with the blood in order to avoid damage to the cellular elements. Even the tonicity factor is commonly ignored when it is desired to administer hypertonic solutions for the purpose of causing dehydration of the patient.

All the firms have agreed to make their buffered solutions of dextrose acceptable by elimination of the buffer in the formula or of the buffer solution packaged with the dextrose solution or to withdraw them from active promotion except Eli Lilly and Company. This concern has admitted that it has no evidence to support the addition of buffers to dextrose solutions but on the ground that there is a demand from the trade for its buffered preparations it will continue to market them.

The Council voted to discontinue the acceptance of all brands of dextrose solution with buffers and to omit them from N N R because of the lack of evidence for buffering dextrose solutions.

## ACTIVE IMMUNIZATION AGAINST TYPHUS

Typhus is an invariable accompaniment of war and famine. Although accurate information on typhus in this war is not yet available, it seems to be increasing in the Balkans, Spain, Poland and the regions about the Russo-German fronts. There are rumors that the disease is spreading in Germany from infected soldiers, though the claim is made that the menace has been banished from Germany.<sup>1</sup>

Ever since the recognition of *Rickettsia prowazekii* as the causative agent, attempts have been made to develop a vaccine suitable for the large scale active immunization of exposed populations. Numerous preparations obtained from human beings, guinea pigs, lice, mice and fleas have been tried. However, today the field has largely narrowed—as far as is known outside of Russia or Germany—to three methods of producing typhus vaccine: Weigl's louse intestine vaccine, Castaneda's mouse or rat lung vaccine and Cox's yolk sac vaccine.

Weigl<sup>2</sup> attempted active immunization by using the phenolized intestinal contents of lice infected by rectum with *R. prowazekii* obtained from the brains of infected guinea pigs. The technic of injection is difficult. Since two or three hundred lice are necessary to provide sufficient vaccine for one person, large scale immunization is difficult. However, these vaccines, composed of killed rickettsias, have been found protective for experimental animals. Although the results have been reported as less satisfactory in man, Weigl's vaccine seems to have been clinically valuable as employed in Poland,<sup>3</sup> Slovakia<sup>4</sup> and Ethiopia.<sup>5</sup>

Castaneda's<sup>6</sup> mouse or rat lung vaccine, prepared from a Mexican murine strain, can be produced in

reasonable quantity. Experimentally this vaccine seems to produce a high degree of immunity. Castaneda has also shown that the vaccine, when prepared from an endemic strain, will protect against infection by the classic strain of European typhus. Dyer,<sup>7</sup> commenting on Castaneda's vaccine, admits that it has been shown to protect man against subsequent inoculation with infectious material, but he points out that neither this vaccine nor the others have yet been thoroughly tested under controlled conditions in the presence of a typhus epidemic.

The most generally favored vaccine is that prepared by Cox<sup>8</sup> from the growth of rickettsias in the yolk sac of developing chick embryos. By this method pure suspensions of rickettsias may be obtained from the yolk sac of infected eggs by centrifugation. Inactivation may be accomplished by the addition of phenol and solution of formaldehyde. Vaccine sufficient for 25 or 30 persons can be obtained from 14 embryos—a practicable quantitative result.<sup>9</sup> The potency of this type of vaccine is usually tested by injecting intraperitoneally at weekly intervals three doses of 1 cc each into guinea pigs. This serves to protect guinea pigs against 1,000 to 10,000 infective guinea pig doses of *R. prowazekii* in the form of infected guinea pig brain. The complicating effect of this course of vaccination on the Weil-Felix reactions and neutralizing antibodies of human beings on whom it has been employed may be due, in part at least, to the size of the dose. However, the only large scale trial of this method of vaccination has been in Spain by Rockefeller Foundation workers. Unfortunately their departure in 1941 did not allow a sufficient period of observation for evaluation of the results. Many more have been inoculated since then.

Spanish observers believe it has helped to control the spread of the disease.

Little is now known concerning the incidence of typhus or the means attempted toward active immunization in any of the other countries most likely to be involved. The Germans are said to be employing a vaccine the nature of which is uncertain. Whether this is restricted to use in Germany or is also used in the Balkans and Poland is not known. Almost certainly the Russians are employing various methods to control the spread of typhus, but whether or not this includes active immunization, what vaccine is employed and what the results have been to date are not known outside that country.

The War Department of the United States has issued a directive<sup>10</sup> to the effect that all military personnel stationed or traveling through areas in which there is

danger from epidemic typhus are to be minimized with typhus fever vaccine prepared by the Cox yolk sac culture method. The initial vaccination is to consist of three injections of 1 cc each, administered subcutaneously at weekly to ten day intervals. Subsequent vaccinations of a single 1 cc dose are to be administered every four to six months as long as serious danger of infection is present and other single doses may be given whenever in the opinion of the surgeon this additional stimulation of immunity is indicated.

The value of typhus vaccination has not yet been definitely established. One of the major difficulties has been the lack of a suitable experimental animal, though the eastern cotton rat may prove to be such an animal.<sup>11</sup> Adequate controlled clinical trial is also necessary and this too is lacking. Pending acceptable information of this nature none of the vaccines available in this country can be considered acceptable for routine mass administration. The War Department recommendations seem sound, other preventive measures involve satisfactory diets, avoidance of overcrowding and the maintenance of an adequate, trained personnel and mobile delousing equipment for use in emergencies.

#### THE HERITAGE OF CONNECTICUT MEDICINE

The Connecticut State Medical Society is celebrating its one hundred and fiftieth anniversary. Again medical history has been enriched by the publication of a volume commemorating the occasion. The Connecticut State Medical Society was granted a charter in May 1792 after representative practitioners tried for nearly thirty years to convince the legislators that it would be in the public interest. The originator of the idea for a formal medical organization in Connecticut is not known. However, the New Haven County Medical Society still has the minutes of every meeting held since Jan 5, 1784. The first volume of medical transactions issued in this country was published by the Medical Society of New Haven in 1788 in a report of observations on 26 cases by various practitioners. Colonel Leverett Hubbard, the first president of the state society, also commanded the second regiment of militia from 1773 to 1775. "The peaceful laurels to be won in a daily routine of calomel, ipecac and bark were not sufficient for his ardent temperament." Mainly through the efforts of pastors a collegiate school was established at Saybrook in 1701, which after its transfer to New Haven developed into Yale College.

Poorly trained practitioners were numerous, and charlatanry was rife. Ezra Stiles, Yale's president, believed that the teaching of medicine was an obligation of his college. He obtained the advice of physicians in planning a medical curriculum but did not live to see it realized. Timothy Dwight, the next president of

Yale, consulted with the Connecticut State Medical Society in the development of plans for a medical school. Nathan Strong, a minister, induced the Yale corporation to appoint a committee to look into the possibilities of establishing medical professorships and to confer with the Connecticut State Medical Society. The plan was adopted and presented by the joint committees to the legislature, which in 1810 empowered the state medical society to join with Yale in forming the "Medical Institution of Yale College." In the next autumn thirty-seven medical students presented themselves for instruction.

Thomas Lord of Hartford was the first physician licensed to practice by the general court, which also established a fee table. "For visit to any house in Hartford, 12 pence, in Windsor, 5 shillings, in Farmington, 6 shillings." Dr Bryan Rosseter seems to have performed the first recorded necropsy in Connecticut about 1662. He was voted twenty pounds by the general assembly for "opening Kellies child," who in her delirium, possibly the result of bronchopneumonia, had cried out against a local witch. To Dr Jared Eliot, who was also a preacher, the church offered sixty cords of firewood a year if he would marry, which he promptly did. Of his eleven children, three became physicians. Dr Eliot, who was the first graduate of Yale to be elected a trustee of the college, in his will, left "ten pounds of lawful money, the interest of which shall be applied to the use of the library," and that was the beginning of the Yale Library fund. Of Dr John Winthrop Jr, governor of Connecticut for many years, the historian has written "He was the finest flower of New England aristocracy." Among other famous practitioners were Samuel Mather Jr, Alexander Wolcott and Elisha Perkins, whose announcement of the "discovery" of the Perkins metallic tractors in 1775 to the Connecticut Medical Society was received "with doubt and caution" and by some members "even with contempt." Dr Elisha North was one of the first advocates of vaccination and the first in this country to open an eye infirmary. Dr Elihu Hubbard Smith of Hartford belonged to a group called "the Connecticut Wits," which started the first real literary movement in America. He was preeminent also in editing the first medical journal published in this country, and he composed an opera in three acts, which was produced in 1794. Dr Smith died of yellow fever in the great epidemic of 1798. Dr William Beaumont, the young army surgeon and pioneer American physiologist, was born in Lebanon, Conn. The list of great names in American medicine could be lengthened down the years by many additions from Connecticut, including Drs William Henry Welch and William H. Carmalt.

In this interesting anniversary volume, the development of physiology, public health, surgery, psychiatry and medical licensure in Connecticut is reviewed. Connecticut's sesquicentennial celebration came to a climax.

<sup>11</sup> Fosdick, R. B. The Rockefeller Foundation—A Review for 1941

in the meeting at Wesleyan University in Middletown, June 3-4, under the presidency of Dr James Douglas Gold. Wednesday morning was given over entirely to clinical medicine by the various sections. Wednesday noon there was a president's luncheon and in the afternoon a meeting, before which "Medicine of the Present and the Future" was discussed. On Thursday morning the historical meeting was attended by the governor of Connecticut, the president of Wesleyan University and the mayor of Middletown. Addresses were delivered by Dr Howard W Haggard of Yale University on "Connecticut Colonial Medicine" and by Drs Creighton Barker and Stanley B Weld, executive secretary and editor, respectively. The convocation on Thursday afternoon was attended by the chairman of the Board of Trustees of the American Medical Association, Dr Arthur W Booth of Elmira, N Y, and was addressed by Dr Logan Clendening of the University of Kansas School of Medicine, on "Opposition to Change as a Contribution to Social Progress." The Connecticut State Medical Society exercised its ancient privilege at this meeting of conferring honorary degrees of medicine on Dr Alice Hamilton and Dr Yandell Henderson. The speaker at the anniversary dinner Thursday evening was the President-Elect of the American Medical Association, Col Fred W Rankin, M C, U S Army.

Thus was celebrated the 150th anniversary of the fourth state medical society to be established in America and the third to have had continuous existence since its founding. Among many others, much credit is due to the sesquicentennial committee, of which the chairman was Dr George Blumer, the vice chairman, Dr Herbert Thoms, chairman of the historical program, Dr David R Lyman, of public relations, Dr C Charles Burlingame, of historical exhibits, Dr Arthur H Jackson, of the scientific program, Dr Francis G Blake, of the local arrangements and annual dinner, Dr Roy L Leak.

## Current Comment

### EVERY DRUGSTORE A VENEREAL DISEASE FIRST AID STATION

Philadelphia pharmacists, in a statement<sup>1</sup> signed by several Pennsylvania physicians and pharmaceutical leaders, are being urged, in effect, to utilize their stores as prophylactic stations against venereal disease. The drugstore is often the social center of a neighborhood. It is suggested that the socially minded head and personnel of such establishments can "(a) discourage off-color frequenters looking for pick-ups and trouble, (b) give friendly advice and even sober counsel to some who are obviously on the way to going wrong, (c) urge blood tests and medical examination on per-

sons who are known to have exposed themselves." The pharmacist is an educator, and the corner druggist's establishment can be as much of a center for public health as a physician's office, hospital or the health department in the city hall. The pharmacist behind the counter has the first chance to give or sell prevention to persons who may expose themselves to venereal disease, to give or sell prevention to persons who have been exposed already, and "to sell the basic idea of a prompt accurate diagnosis and immediate treatment" to persons who describe a symptom or ask for treatment, attempt to purchase a proprietary remedy, tell a story that shows they are taking risks that they do not realize, or that they have consulted a quack. The pharmacist is urged to place the facts and aims of venereal disease control before the public, and the state pharmaceutical association is prepared to supply a card or posters for counter display and booklets for distribution to inquirers.

### KOCH'S CANCER TREATMENT MEETS THE LAW II

A Current Comment in *THE JOURNAL*, April 18, called attention to the fact that the Koch Laboratories in Detroit and the concern's principals "will face charges of violating the Federal Food, Drug and Cosmetic Law on 11 specific charges." Now comes word that the Federal Trade Commission has also entered the picture. At the time of the Wheeler-Lea Amendment to the Federal Trade Commission Act there was some conjecture as to whether or not it was advisable to have the advertising which was a part of the package come under the purview of the Food and Drug Administration, and all collateral advertising—newspapers, magazines, utterances by radio and mailing—under the purview of the Federal Trade Commission. In this particular instance there is no question as to its advisability. Reproduced herewith is a release of the Federal Trade Commission which requires no further comment.

### TEMPORARY RESTRAINING ORDER

Medicines, Friday, May 22, 1942

Judge O'Brien, of the United States District Court for the Eastern District of Michigan, Detroit, today (May 22) granted a temporary restraining order upon application of the Federal Trade Commission, requiring William F Koch, Louis G Koch, and Koch Laboratories, Inc., 8181 East Jefferson Ave, Detroit to cease disseminating false advertisements concerning medicinal preparations designated "Glyoxylide," "B-Q," and "Malon de Ketene Solution."

The defendants are required to show cause on May 27 why a preliminary injunction should not be issued without bond to restrain them from disseminating the advertisements alleged pending issuance of a complaint against them by the Federal Trade Commission and until its final disposition.

The temporary restraining order of the court requires that two individuals and Koch Laboratories, Inc., until May 27, to cease advertising that Glyoxylide is a competent or effective preparation for use in treating any type or stage of cancer, arteriosclerosis, dementia praecox, epilepsy, tuberculosis, caemia, insanity and other ailments, that "B-Q" is effective for use in treating any infection including gonorrhea, meningitis, infantile paralysis, streptococcus sore throat, pneumonia, and other diseases, and that Malonide Ketene Solution is effective for treatment of allergic diseases, infection, cancer, double pneumonia, or post operative meningitis.

# MEDICINE AND THE WAR

*In this section of The Journal each week will appear official notices by the Committee on Medical Preparedness of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession*

## TWENTY-EIGHT MILLION SURGICAL DRESSINGS MADE BY RED CROSS WORKERS

Between the beginning of September 1939 and the 1st of October 1941 the American Red Cross spent \$49,753,515 on war relief in Europe, Asia and the Middle East. This sum does not take into account the medical, surgical and hospital supplies—estimated at a value of \$200,000—shipped to Russia from Great Britain in behalf of the American Red Cross.

The relief work thus accomplished during the past twenty-five months of the war has been made possible by gifts from the American people and by supplies purchased by the United States government for foreign war relief. Volunteer workers in American Red Cross chapters have played a large part in this work. According to the League of Red Cross Societies they have produced nearly six and a half million articles of clothing and 28,331,772 surgical dressings. These workers have furnished Great Britain alone with 21,786,000 dressings, 565,000 hospital garments, 1,630,000 sweaters, 879,000 other knitted garments, 1,459,000 children's garments, 511,000 articles of clothing for women, 253,000 layettes and 39,000 women's kits. More than eleven hundred thousand blankets have been sent to various countries for the wounded and for homeless civilians.

## MEDICAL DEPARTMENT OPENS NEW SCHOOL

A new school devoted entirely to the training of medical administrative corps officers was opened on May 9 at Camp Berkeley, Texas. Lieut Col G E Armstrong, assistant commandant under Brig Gen Roy C Heflebower, camp commander, will have direct charge of instruction. Major Charles L Driscoll of the medical administrative corps now at Fitzsimons General Hospital, Denver, will be assigned to the new school, as will be the following as heads of departments: Capt Wayne A Starkey, M C, medical tactics; Capt August H Groeschel, M C, training; Capt William H Crosby Jr, M C, chemical warfare; Capt Francis B Elder, S C, military sanitation; 2d Lieut Richard B Quigley, Medical Administrative Corps, logistics. Other schools under the supervision of the medical department are (1) the Army Medical School, Washington, D C which trains officers in military medicine; (2) the School of Aviation Medicine, Randolph Field, Texas, which trains flight surgeons; and (3) Medical Field Service School, Carlisle Barracks, Pa, which trains medical department officers in field work and military duties.

## CIVILIAN DEFENSE

Dr John B Alsever, formerly of Syracuse N Y, and now of Washington, D C, arrived in San Francisco, April 27, to assist Dr Leonard A Scheele, regional medical officer of the Office of Civilian Defense, in setting up blood banks in Pacific Coast hospitals.

Dr Arthur E Lewis of Seattle, assistant state medical officer for civilian defense, returned from Cincinnati April 27, where he took a course in chemical warfare. Dr Lewis will speak throughout the state to Emergency Medical Service units, defense coordinators and in hospitals. Dr Donald G Evans, state chief of the Emergency Medical Service in cooperation with the state defense council, is creating medical areas throughout Washington so that smaller communities may draw on the large cities for medical supplies and personnel in case of air raids.

At nine mass meetings in Tacoma, Wash., April 27, sufficient contributions were made by citizens to equip the ten emergency hospitals which have been located in the public schools. The Red Cross had already equipped the twenty-seven casualty stations in Tacoma, which also are located in school buildings.

Dr Herman N Bundesen, Chicago, chief of the Emergency Medical Service for Civilian Defense, announced on May 11 that Mayor Kelly had appointed the following eleven doctors as district medical adjutants for the Chicago metropolitan area: Warren H Cole, loop; Lester R Dragstedt, south side; John A Wolfer, north side; Frederick A Besley, Waukegan; Frederick Christopher, Evanston; Sumner L Koch, Des Plaines; Frederick G Dyas, Wheaton; James H Skiles, Cicero; Eli S Jones, Gary; Charles F Sawyer, Harvey; and Harry A Oberhelman, Oak Park.

## INDIANA'S GENERAL HOSPITAL UNIT

Special ceremonies were held on May 12 at the James Whitcomb Riley Hospital, Indianapolis, in recognition of the 32d U S Army General Hospital unit formed at Indiana University Medical Center. Already forty-two physicians and five dentists have received their commissions. When completed, there will be attached to the 32d General Hospital unit about seven hundred persons including one hundred and twenty nurses. Drs Cyrus J Clark and Charles F Thompson, both of Indianapolis, who have been in charge of organizing the unit, have been commissioned lieutenant colonels.

At the ceremony were Governor Henry F Schricker, Mayor Reginald H Sullivan, President Herman B Wells of Indiana University, William L Bryan, president emeritus, and Dr W D Gatch, dean of the university medical school, who presided. The military ceremony was conducted by Col R L Shoemaker, commanding officer of the Indiana University R O T C, and the oath of loyalty was administered by Lieut Col I F Peak, commander of the medical school R O T C. In the first world war Base Hospital No 32 was organized at Indiana University Medical School in cooperation with the City Hospital and the American Red Cross.

## COMMISSIONS FOR DENTAL AND VETERINARY STUDENTS

The War Department, Washington D C, April 17 granted authority to corps area commanders to waive the provisions of paragraph 5 AR 140-33 for the appointment as second lieutenant Army of the United States (Medical Administrative Corps) of physically qualified male citizens of the United States above the age of 18 years who are bona fide accepted matriculants at approved dental and veterinary schools within the United States. Officers so appointed will not be ordered to active duty until eligible for appointment as first lieutenant Army of the United States (Dental or Veterinary Corps).

Appointment will be made without reference to an examining board as prescribed in paragraph 20 c, AR 140-5 and without reference to procurement objectives.

Applications and accompanying papers as prescribed in AR 605-10 will be forwarded by the dean of the dental or veterinary school to the commanding general of the corps area in which the school is located together with a certified statement that the applicant is a bona fide accepted matriculant in dentistry or veterinary medicine at the institution.

Officers appointed under these provisions will be discharged for the convenience of the government under the full pay and

cumstances (1) discontinuance of dental or veterinary education, (2) matriculation at an unapproved school of dentistry or veterinary medicine, (3) failure to complete successfully the prescribed four year course of dental or veterinary instruction, (4) failure to secure appointment in the Army of the United States (Dental or Veterinary Corps) within three months after completion of the prescribed four year course of dental or veterinary instruction

Students at approved schools of dentistry and veterinary medicine who already hold reserve commissions in other arms or services will not be ordered to active duty until they successfully complete the prescribed four year course of dental or veterinary instruction. In the latter event they may be transferred to the Dental or Veterinary Corps Reserve in the grade of first lieutenant

#### SOCIETY OF MEDICAL DEPARTMENT OFFICERS AT FORT DEVENS

The Fort Devens Society of Medical Department Officers will be addressed, June 16, by Dr. Alan Moritz, professor of legal medicine, Harvard Medical School, Boston, on "Observations on the Pathology of Mechanically Produced Injuries." The society was addressed, June 2, by Dr. Ernest E. Tyzzer of Harvard Medical School on "Tropical Medicine", May 19, by Lieut. Col. William F. McPhee, chief of the surgical service of the second evacuation hospital, on "Pilonidal Sinus," and, May 5, by Dr. Herman C. Pitts of Providence, R. I., on "Treatment of Cancer of the Cervix." This organization meets on the first and third Tuesday of each month and is attended by the medical department officers stationed at Fort Devens. The society was organized in 1939.

#### MEDICAL COLLEGE OF VIRGINIA HOSPITAL UNIT

U. S. Army General Hospital Unit No. 45, formed at the Medical College of Virginia, Richmond, has been ordered to report at a camp for training preparatory to service abroad. When completely organized, the unit will include seventy-two medical and technical personnel from the staff of the Medical College of Virginia, a corps of enlisted men furnished by the Army Medical Department and more than a hundred nurses. While most of the physicians and dentists are from Richmond, some are from Norfolk, Lynchburg, Roanoke, Fredericksburg, Petersburg and Scottsville. In charge of organization of the unit have been Drs. John Powell Williams and A. Stephens Graham, both of whom have been commissioned lieutenant colonels. During the first world war, Base Hospital No. 45 was organized at the Medical College of Virginia under the leadership of the late Dr. Stuart McGuire of Richmond, and that unit performed distinguished service on the battlefields of France.

#### BLOOD BANKS IN PENNSYLVANIA HOSPITALS

A survey of Pennsylvania hospitals discloses that there is a total reserve of blood and plasma sufficient for treatment of only 2,775 civilian casualties in an emergency, the State Defense Council has reported, according to an article in the *Harrisburg Telegraph*. Dr. Paul Dodds, chief medical officer, said that two hundred and eight hospitals of fifty beds or more from which replies were received in a blood survey included sixty-eight with reserves beyond their regular needs, twenty-one with banks but without emergency reserve and one hundred and nineteen not maintaining banks. Twelve large hospitals of two hundred beds or more are without blood banks.

#### REGISTRATION OF DISTRICT DOCTORS

The District of Columbia Procurement and Assignment Committee conducted the registration of all licensed physicians in the district, May 12, in order to determine the number available for military service and those available for the care of the civilian population in the district. The Office of Civilian Defense

provided thirty-five clerks to conduct the registration, which was carried out at the building of the District Medical Society, 1718 M Street N.W. Some of the clerks also were stationed at the various hospitals in the district. The chairman of the committee is Dr. Francis X. McGovern. The registration was voluntary. Physicians who were out of town at the time were expected to register at the medical society office on their return.

#### RECEPTION SERVICE FOR RETURNED SOLDIERS AND SAILORS

Governor Green announced on May 15 that the state of Illinois is establishing a reception service for returned soldiers and sailors of the present war. He has instructed the director of public welfare to secure the names of all men released from the armed services, of whom about one hundred and fifty soldiers, most of whom are mentally ill, have already returned to the state. The division of veterans' service will get in touch with these returned men, guide them in securing medical and hospital services and proper allowances for disability, and assist in finding employment when such is possible.

#### NEW CHIEFS FOR HEALTH SUPPLIES BRANCH OF WAR PRODUCTION BOARD

Mr. Francis M. Shields, Miami Beach, Fla., formerly vice president of the American Optical Company, Southbridge, Mass., has been appointed chief of the Health Supplies Branch of the Division of Industry Operations of the War Production Board. Mr. William M. Bristol Jr., formerly chief of this branch, has resigned to rejoin his own company. Mr. Fred J. Stock, who has been associated with the Health Supplies Branch as an industrial commodity specialist, has been appointed deputy branch chief. He was formerly an official of the Walgreen Drug Company, Chicago.

#### EMERGENCY DISTRICT CENTERS IN SACRAMENTO

Nine district centers are now ready at Sacramento, Calif., to provide in an emergency everything from medical care to reuniting lost children with families, the *Sacramento Bee* reports. The centers function under the defense council, and one thousand men and women are ready to operate them. The centers will provide food, shelter, clothing, first aid, registration of the injured and emergency transportation. The centers go into action only in a major emergency when normal facilities for such services become inoperative. An educational campaign will be launched to acquaint the citizens with the locations of the nearest district centers.

#### DR. BOUSFIELD IN CHARGE OF HOSPITAL UNIT

Dr. Midian O. Bousfield, member of the Chicago Board of Education and for nine years director of Negro health under the Julius Rosenwald Fund, will leave on June 7, according to the *Chicago Sun*, to take charge of an all Negro medical and nursing unit which will provide the staff for an army hospital in a southwestern state. The personnel has been recruited largely from the Provident Hospital in Chicago. Among the other medical officers in the unit will be Majors Harold Thatcher, John West and Maurice Shaw, Capt. Arthur V. Thomas and Clarence Jamison and First Lieutenants Earl Shepleard and Joseph Mitchell.

#### BLOOD BANKS IN WEST VIRGINIA

The state health commissioner, who is chief of the Emergency Medical Service in West Virginia, has appointed Dr. John W. Crosson to take charge of setting up blood banks in emergency base hospitals in strategic areas of the state and in Wheeling, Huntington and Charleston. To qualify, the hospitals must be approved and have at least a capacity of two hundred beds. When designated they may receive up to \$2,000 to defray expenses of setting up blood banks.

## OFFICIAL NOTES

### THE ATLANTIC CITY SESSION

#### Radio Program

Arrangements for radio broadcasts in connection with the annual session of the American Medical Association at Atlantic City have been completed.

The weekly dramatized program *Doctors at Work* on the network of the National Broadcasting Company will close with the broadcast scheduled for Saturday, June 13, at 5 p m eastern time.

In addition, the following programs have been scheduled for broadcasting by National Broadcasting Company and Columbia Broadcasting System networks, the Blue Network and local stations in Atlantic City (eastern time)

WFIL (Blue Network), Monday June 8, 2 p m Dr J Harry Murphy, Omaha Childhood type tuberculosis

WBAB (C B S), Monday, June 8, 4 p m Col F W Rankin, M C, U S Army, Louisville, Ky 'Your Doctor's Responsibilities in Wartime'

N B C, Tuesday, June 9, 12 30 p m Dr Frank H Lahey, Boston "The Place of Medicine Today"

WBAB, Tuesday, June 9, 2 30 p m Dr Irwin Schulz Injuries in children

WFGP, Tuesday, June 9, 7 45 p m Dr Don Carlos Peete, Kansas City, Kan Acute rheumatic fever

WBAB, Wednesday, June 10 See local papers for time Round table discussion "Doctors at War" Dr George Baehr, Washington, D C, Dr Willis S Knighton, New York, Rear Admiral H W Smith, M C, U S Navy, Washington, D C, Dr Charles S White, Washington, D C, and Dr W W Bauer, Chicago

N B C, Thursday, June 11, 6 30 p m Dr W W Bauer, Chicago Convention news

WFGP, Thursday, June 11, 7 45 p m Dr Elmer H Loughlin, Brooklyn Pneumonia

## MEDICAL ECONOMIC ABSTRACTS

### FEDERAL AND STATE AID

A rapid and far reaching centralization in financial administration in recent years is traceable to the accelerated growth in the amounts given by the federal government to the states and by the states to local governments<sup>1</sup>. In 1941 \$851,000,000, or 10.7 per cent of the total federal revenues, was distributed in the form of aid. Of this amount \$744,000,000 was paid to states, \$96,000,000 was paid to local governments and \$11,000,000 to territorial governments.

This is a comparatively recent development in public finance. Although federal aid has been given for education, agriculture and highways for many years, the total amount of such aid distributed in 1925 was only \$113,600,000. While federal aid for all the aforementioned purposes has increased the most rapid growth has been in public assistance, which amounted to \$155,000,000 in 1937 and to \$331,000,000 in 1941. Under this classification \$259,000,000 constituted aid to the aged.

The following sums were given to aid public health

|                           |              |
|---------------------------|--------------|
| Crippled children         | \$ 5 071 000 |
| Maternal and child health | 3 739 000    |
| Public health work        | 10 284 000   |
| Venereal disease control  | 5 483 000    |
| Total                     | \$24 577 000 |

That this movement toward the centralization of finance is not confined to the federal government is evidenced by the increase in the aid given by states to local governments from \$535,800,000 in 1925 to \$1,697,800,000 in 1941. Education still receives the largest share of state aid but public assistance has shown the most rapid growth in recent years. This is partly due to more extensive participation by the states in all forms of public assistance and especially to payments for the categorical forms of public assistance—old age assistance aid to dependent children and aid to the blind—which consist almost exclusively of unemployable people. In some states of which Pennsylvania is an outstanding example the state has taken over functions formerly performed by elected county officials so that the county boards are in reality state agencies working directly under the state department of public assistance.

<sup>1</sup> Federal and State Aid, 1941 U S Department of Commerce Jesse H Jones Secretary State and Local Government Special Study No 19 April 1942

### FARM SECURITY PLAN IN OKLAHOMA

That there is considerable dissatisfaction with the working of the farm security plan for medical care is indicated in the report of the Committee on Medical Economics to the House of Delegates of the Oklahoma State Medical Association which says

"In the main the reports from the different societies were to the effect that the programs were not satisfactory for reasons of administration, inequalities and low fee payments for services rendered.

"Upon meeting with F S A representatives concerning this program, certain objectionable features seemed to have been eliminated, but your committee at this time cannot report further upon the attitudes of the county societies concerning the operations of the plans under the revised system.

"Your committee recommends that no endorsement of the Farm Security Administration plans be made by the House of Delegates, but that the cooperation of organized medicine be left to the discretion of the local county societies after careful and complete study.

### EFFECT OF THE WAR ON CLINIC VISITS

An increase in employment accompanying the economic changes attendant on war activity is apparently responsible for a rapid decline in the number of visits to Milwaukee clinics. A report of the Milwaukee County Community Fund and Council of Social Agencies found that while there were nearly 128,000 such visits during the last quarter of 1940 there were only 91,000 in the corresponding months of 1941—a decline of over 25 per cent. The decline was 33 per cent in public and 12 per cent in private clinics.

Data for January and February 1942 indicate that the rate of decline is increasing for most of the clinics. In explanation of this trend the council says: "In recent months men have reentered industry who formerly were on relief or barely getting by. Many families whose incomes were formerly qualified them for clinic care a year ago now have incomes which place them outside of the group entitled to health agency clinic care."

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

### CALIFORNIA

**Examinations to Fill Laboratory Positions**—The California State Personnel Board has announced that applications will be received from citizens throughout the United States for the position of chief, bureau of laboratories (entrance salary \$360 a month), and assistant chief, bureau of laboratories (entrance salary \$320 a month), in the state department of public health. The requirements for the position of chief are graduation from a college of medicine, five years' experience in a laboratory devoted to bacteriologic and chemical work, and ability to obtain a medical certificate in the state of California. The entrance requirements for the position of assistant chief are the equivalent of three years of graduate study in bacteriologic science and two years' experience in a public health laboratory in a biologic producing laboratory, in an educational institution laboratory producing, testing or analyzing biologic preparations or as a teacher of bacteriology in a university. Application forms and information may be obtained from the California State Personnel Board, 1015 L Street, Sacramento. Applications must be filed by June 30.

### FLORIDA

**Venereal Control Officer**—Dr Wilson T Sowder, Tampa, U S Public Health Service, who was health officer of Hillsborough County, has been placed in charge of the bureau of venereal disease control of the state board of health. He succeeds Dr Leo C Gonzalez, Jacksonville, who has been in charge of the work for the last four years and who, it is reported, was to retire on May 1 to engage in private practice in Tampa.

**Annual Graduate Course**—The Florida Medical Association and the state board of health will conduct their annual graduate short course for doctors in medicine at the George Washington Hotel, Jacksonville, June 22-27. Included among the instructors will be Drs Nicholson J Eastman, professor of obstetrics Johns Hopkins University School of Medicine, Baltimore, Edward W Alton Ochsner, William Henderson professor of surgery, Tulane University of Louisiana School of Medicine, New Orleans, and Robert W Wilkins, assistant professor of medicine at Harvard Medical School, Boston.

### GEORGIA

**Industrial Hygiene Service**—The Georgia State Department of Health recently created an industrial hygiene service in its division of preventable diseases with Dr Lester M Petrie, Atlanta, as director.

**State Medical Election**—Dr William A Selman, Atlanta, was named president-elect of the Medical Association of Georgia at its annual meeting in Augusta, April 28-May 1, and Dr James A Redfearn, Albany, was inducted into the presidency. Other officers include Drs Samuel J Lewis, Augusta, and Cleveland Thompson, Metter, vice presidents. Dr Edgar D Shanks, Atlanta, was reelected secretary. The next annual meeting will be in Atlanta, May 11-14.

**District Meetings**—The Seventh District Medical Society was addressed at Dalton, April 1, among others, by Drs Hal M Davison, Atlanta, on "Management of the Asthmatic Patient" and Frederick B Ragland, Dalton, "Treatment of Abortions"—Dr Seale Harris, Birmingham, addressed the Fifth District Medical Society in Atlanta, April 6, on "Endocrinopathies and Carbohydrate Metabolism"—The Eighth District Medical Society was addressed in Valdosta, April 14, among others, by Dr Charles M Carpenter, Rochester, N Y, on "Community Control of Gonorrheal Infection."

### ILLINOIS

**Changes in Health Personnel**—Dr Reuben F Reider, New York, U S Public Health Service, has been named health officer of the Champaign-Urbana health district, succeeding Dr Walter C Earle, Champaign, who has been granted a leave of absence to do special work for the federal government, it is reported—Dr Henry C Scholer has been named health officer of Monmouth, succeeding Dr James W Firoved, who resigned to enter the medical corps of the navy.

### Chicago

**Reunion at Illinois**—The alumni-faculty-student smoker of the University of Illinois College of Medicine will be held June 11 at 6 30 p m at the Chicago Illini Union. Reservations may be made with the Medical Alumni Association, 1833 West Polk Street. Dr Michael H Streicher is the secretary.

**Alumni to Dine with Last Class at Rush**—The alumni banquet of Rush Medical College will be held in the Red Lacquer Room, Palmer House, June 13, at 6 30 p m. The occasion will mark the graduation of the last class of Rush Medical College. Dr Morris Fishbein, Editor of THE JOURNAL, will deliver the principal speech, on "Military and Civilian Aspects of Medicine in War."

**Neuropsychiatric Institute Dedicated**—The Illinois Neuropsychiatric Institute on the grounds of the Illinois Research and Educational Hospital is being formally dedicated June 6. Dr Harry R Hoffman, executive officer, is presiding. Dr Edward A Strecker, professor and head of the department of psychiatry, University of Pennsylvania School of Medicine, Philadelphia, and president-elect, American Psychiatric Association, is delivering the principal address entitled "Neuropsychiatric Perspectives." Dr Ralph C Hamill will deliver a

Illinois Neuropsychiatric Institute

tribute to the late Willoughby G Walling, chairman of the board of welfare commissioners, whose idea it was that the institute's facilities be available for teaching and research to all qualified medical schools in the state. A L Bowen, Springfield, will offer a tribute to the late Dr Harold Douglas Singer. Other speakers will include Arthur Cutts Willard LL D, president of the University of Illinois, and Gov Dwight H Green, Springfield. Three bronze plaques will be unveiled and dedicated to the memories of Dr Singer, the late Governor Henry Horner and Mr Walling. The unit which was constructed as a joint project of the state department of public welfare and the University of Illinois, with the financial assistance of the PWA, cost more than \$1,500,000. Dr Francis J Gerty was chosen by the university as director of the psychiatric division and Dr Eric Oldberg as director of the neurologic and neurosurgical divisions. The institute is composed of three distinct but interrelated units. The north tower houses organic neurology, the south tower houses psychiatry, the air conditioned ground or basement floor contains the physiologic unit. Each nine story tower is an independent hospital, research and teaching institute. The psychiatric unit has facilities for 98 patients, including those for 14 children. The children's ward will be directed by Dr Paul L Schrier, who will have immediate charge of the conduct of treatment, research and teaching. The neurologic tower has a capacity of 54, including facilities for 3 infants and 9 children.

**Portrait of Dr H Douglas Singer**—A portrait of the late Dr Harold Douglas Singer professor of psychiatry at the University of Illinois College of Medicine, was presented to the university at a memorial dinner in the Chicago Illinois Union on May 27. Dr Francis J Gerty, head of the department of psychiatry, presided. A L Bowen, Springfield former director of the state department of public welfare gave the address of presentation. Dr David J Davis, dean of the medical school delivered the address of acceptance and the psychiatric staff under the chairmanship of Dr Alfred P Solomon presented a sketch "As We Knew Dr Singer." The portrait was painted by Mrs Lucile Stevenson Dalrymple from photographs. The cost was met by contributions from friends and associates. Dr Singer was made director of the newly created Illinois State Psychopathic Institute in 1907. In 1917 he was appointed state alienist and was at the same time special examiner for the Illinois Exemption Board and advisory consultant in neuropsychiatry to the surgeon general of the U S Public Health Service. He was also advisory consultant to the U S Veterans Bureau. At the time of his death in 1940 he was president of the American Board of Psychiatry and Neurology, president of the American Neurological Association and president-elect of the American Psychiatric Association.

### MAINE

**State Medical Meeting**—The ninetieth annual session of the Maine Medical Association will be held at the Poland Spring House, Poland Spring June 21-23, under the presidency of Dr Perry L B Ebbett, Houlton. A tentative program lists the following speakers:

Rev George W Shepherd Boston The Battle for Freedom in China and India  
Dr Joe V Meigs, Boston Endometriosis Its Etiology Symptoms and Treatment  
Dr Howard T Karsner Cleveland (Subject not announced)  
Dr Merrill C Sosman Boston Observations on Reversible Heart Disease  
Dr Samuel C Harvey New Haven Surgery of the Sympathetic System  
Dr Chester S Keefer Boston Differential Diagnosis of Obscure Cases  
Dr Delmer Allan Craig Bangor Medical Aspects of Civilian Defense

There will be conferences on traumatic surgery and other subjects. On Tuesday evening the annual banquet will be addressed by Dr Morris Fishbein, Chicago, Editor of THE JOURNAL, on "Medicine and the War." Presentation of the fifty year medals will take place at this time.

### MARYLAND

**New Secretary of State Society**—Dr William Houston Toulson, professor of genitourinary surgery, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, was chosen secretary of the Medical and Chirurgical Faculty of Maryland at the annual meeting April 28-29, to fill the unexpired term of Dr Richard T Shackelford, Baltimore who has entered army service. Dr Robert Lee Hall Pocomoke City is president. It was also decided to cancel the semiannual meeting of the society, usually held in the early fall.

**Personal**—Dr Huntington Williams commissioner of health of the city of Baltimore, who studied air raid medical administration in England for the Office of Civilian Defense recently spoke on this subject at the annual postgraduate clinic at George Washington University School of Medicine, Washington, D C.—Elsa Orent Keiles, ScD, formerly of the department of biochemistry, Johns Hopkins University School of Hygiene and Public Health, Baltimore, is now in charge of the nutrition research laboratories and assistant chief of the foods and nutrition division of the Bureau of Home Economics, U S Department of Agriculture, Beltsville Research Center, according to Science.

### MICHIGAN

**Graduate Work for Physicians**—The Michigan State Medical Society in cooperation with the Wayne University College of Medicine, Detroit the University of Michigan Medical School, Ann Arbor and the Michigan Department of Health, Lansing has arranged a series of meetings to help practicing physicians keep abreast of recent developments in medicine. Weekly conferences made up the program in various places throughout the state. They opened in April and continued until the last week in May.

**Past Presidents' Night**—The Bay County Medical Society marked its past presidents' night, April 8 with a dinner honoring twenty-four physicians who formerly served as president. A gold key was awarded to each one. Dr Charles H

Baker, president of the state medical society in 1919, who served as president of the county society in 1887, is dean of the group. Others at the dinner included Drs William Kerr, Virgil L Tupper, William R Ballard Roy C Perkins, George W Moore, Joseph C Grosjean Rowston E Scrafford, Aloysius J Zarembo Edward C Warren Paul R Urmon, Vanny H Dumond Charles W Ash Matthew R Slattery, Edward S Huckins John H McEwan Sylvester L Ballard, Arthur D Allen Charles L Hess L Fernald Foster Robert H Criswell Relza N Sherman, all of Bay City. Guy M McDowell Howell and Maurice C Miller, Auburn. Dr Foster is now secretary of the state medical society.

### NEW JERSEY

**Diathermy Machine Seized in Alien Raid**—On May 23 newspapers reported that a short wave radio transmitter of the diathermy machine type capable of transmitting messages 50 miles out to sea was seized by Federal Bureau of Investigation agents in one of thirty-eight raids which they made the previous evening on the homes of aliens of enemy nationalities in different sections of New Jersey. The apparatus was found in the home of a 36 year old unmarried German who said he bought the machine for use in treating rheumatism but admitted that he had never consulted a physician concerning such an ailment. The man was arrested. A recent order by the federal communications commissioner directs all owners of diathermy machines to register them with the commission by June 8.

### NEW YORK

**Hospital News**—A fifty-eight bed addition will be constructed to the St Francis Hospital Poughkeepsie, at an estimated cost of \$298,000. About \$100,000 will be available under a federal grant.

**Scarlet Fever Traced to Raw Milk**—About thirty cases of milk-borne scarlet fever occurred between April 6 and April 20 among workers in a cheese plant in Delaware County or among persons using milk obtained from the plant. The bureau of milk of the state department of health is attempting to determine the origin of the infection. All the milk now used in the plant is being pasteurized prior to the processing of the cheese whereas raw milk was largely used in the process prior to the outbreak.

### New York City

**Graduate Courses**—The New York University Graduate School announces the following courses as part of the regular twelve weeks summer session June 29-September 18: biochemistry and nutrition (biology) hematology and microtechnic (biology) advanced laboratory techniques (physics), semimicroqualitative organic analysis (chemistry) and organic synthesis (chemistry).

**Merrit Cash Prize Awarded**—The Merrit H Cash Prize of the Medical Society of the State of New York for the best original essay on some medical or surgical subject has been presented to Dr Emanuel Goldberger for his paper on "The Value and Advantages of Augmented Unipolar Extremity Leads (aV-Leads) in the Diagnosis of Myocardial Infarction (Coronary Thrombosis and Acute Coronary Insufficiency)." The research on which the paper was based was conducted at Lincoln Hospital.

**Changes in Faculty at Long Island College of Medicine**—Dr Fred L Moore has resigned as professor of preventive medicine and community health of the Long Island College of Medicine Brooklyn effective when his successor has been appointed. He has been named director of the division of public health studies of the Commonwealth Fund. The college of medicine announces the promotions of the following Brooklyn doctors to professional rank effective July 1:

Dr Edwin P Maynard Jr medicine  
Dr George Freeman ophthalmology  
Dr Howard F Peakey medicine  
Dr Martin A Murphy medicine  
Dr Charles B Jones surgery  
Dr Mortimer A Laikin ophthalmology  
Dr Louis J Frank dermatology and syphilology

**Three Cents a Day Plan Benefits Increase**—The Associated Hospital Service has announced that the three cents a day plan benefits to member hospitals will be increased from the present rate of \$6.75 to \$7 per day of hospital care received by subscribers on or after July 1. The increase which is subject to the approval of the state department of insurance and social welfare was voted in recognition of the increased cost of hospital service. The present rate of \$6.75 a day has been in effect since Oct 1, 1941 when it was increased from \$6.50.

former daily payment of \$6.50. The Associated Hospital Service also announces that seventy hospital boards with their medical staffs and more than two thousand four hundred individual physicians are now participating in the Community Ward Plan, the new prepayment plan for low income workers which is jointly sponsored by Associated Hospital Service and Community Medical Care, Inc.

**Annual Graduate Fortnight**—"Disorders of the Nervous System" will be the theme of the fifteenth graduate fortnight of the New York Academy of Medicine, October 12-23. The program will include morning panel discussions, afternoon hospital clinics, evening lectures, scientific exhibits and demonstrations. Evening lectures will be delivered by

Dr Timothy Leary, Boston, Pathology of Head Injuries  
Dr Derek E Denny Brown, Boston, Principles of Treatment of Closed Head Injuries

Dr William V Cone, Montreal, Quebec, Canada, Principles of Treatment of Penetrating and Perforating Wounds of the Brain

Dr Eli Jefferson Browder, Brooklyn, Subdural Hematoma (and Other Late Results of Head Injury)

Dr Edward A Strecker, Philadelphia, Military Psychiatry

Dr Harold G Wolff, The Emotions and Disease

Dr Donald Munro, Boston, Tidal Drainage and Cystometry in the Treatment of the Bladder in the Presence of Spinal Cord Injuries

Dr Joseph E J King, Diagnosis and Treatment of Brain Abscess

Dr Gilbert Horrax, Boston, Differential Diagnosis and Prognosis of Brain Tumors

Dr Frank B Walsh, Baltimore, Neuro Ophthalmology

Dr Byron P Stookey, Wounds and Injuries of the Spinal Cord

Dr Francis C Grant, Philadelphia, Surgical Treatment of Pain

Dr Stanley Cobb, Boston, Treatment of Speech Disorders

Dr Tracy J Putnam, Multiple Sclerosis and "Encephalomyelitis"

Dr Charles D Aving, Cincinnati, Limitations of Vitamins in Neurology

Dr Nolan D C Lewis, Present Status of Shock Therapy

Dr Walter Freeman, Washington, D C, Prefrontal Lobotomy

Dr Lawrence S Kubie, Types of Psychotherapy and Indications for Them

Dr Henry A Riley, Migraine and Other Forms of Headache

Dr William G Lennox, Boston, Epilepsy and Its Treatment

## OHIO

**Personal**—Dr Robert M Andre, Waverly, has been appointed supervisor of the medical section of the state industrial commission during the absence of Dr Henry P Worstell, Columbus, now on active duty as a lieutenant commander in the medical corps of the U S Navy. Dr Addison L Kefauver has been named assistant supervisor of the medical section.—Dr Barbara A Hewell, pediatric coordinator of the Cincinnati Anti-Tuberculosis League, has resigned to become specialist in child hygiene in the division of research in child development in the U S Children's Bureau, Washington, D C.—Dr Harold O Crosby, Findlay, coroner of Hancock County, was guest of honor at a dinner given by the county medical society on April 14 to mark his departure for army service. He was presented with a gladstone bag and a traveling clock.

**Traveling Exhibit on "Food for Health"**—The Cleveland Health Museum announces its first traveling exhibit on "Food for Health." Nine units are included in the exhibit. The "Wheel of Life" reveals in essential part protective foods, "How Many Calories" is an exhibit which shows the varying quantities of food needed for work and play, "Why We Eat" illustrates food elements necessary to various parts of the bodily structure, "Food Building Blocks" are especially for elementary class room nutrition. The exhibit "A Nickel's Worth" shows variance of return on money spent for wholesome foods rather than luxury foods and drinks. Twelve food fallacies are illustrated. An exhibit shows how to get double food value for prices which the average buyer pays. The foods are demonstrated in average servings in colored wax models, and most of them have their own individual lighting. Dr Bruno Gebhard is director of the Cleveland Health Museum.

## OKLAHOMA

**Long Memorial Lecture**—Dr Charles W Mayo, Rochester, Minn, recently delivered the third LeRoy Long Memorial Lecture at the University of Oklahoma School of Medicine, Oklahoma City, under the auspices of the Phi Beta Pi fraternity. Dr Mayo's subject was "Principles of Surgery of the Colon."

**Spring Clinical Conference**—The Pottawatomie County Medical Society recently held an annual spring clinical conference at the Aldridge Hotel, Shawnee. Dr Arthur E Hertzler, Halstead, Kan, spoke on "Surgical Aspects of Acute Conditions of the Gallbladder" and Dr Andrew C Ivy, Chicago, "The Physiology of the Gallbladder." In the evening Dr Hertzler discussed "The End Results of Total Thyroidectomy" and Dr Ivy "The Physiology of the Thyroid Gland."

## OREGON

**Change in Meeting Place**—The Oregon State Medical Society will hold its annual session in Portland instead of in Corvallis. The change was made because of the probable inadequate hotel accommodations resulting from increased need of housing facilities. The meeting will be held September 9-11.

## PENNSYLVANIA

**Personal**—Staff members of the Braddock General Hospital, Braddock, gave a dinner recently to honor Dr Harry F Fisher, Braddock, for his completion of fifty years in the practice of medicine. Dr Fisher is chief obstetrician and oldest member of the hospital staff.

**Society News**—Dr Herbert T Kelly, Philadelphia, addressed the Lehigh County Medical Society in Allentown, May 12, on "Nutrition as It Appears to General Disease."—Dr I Newton Kugelmass, New York, discussed "War Nutrition for Children in Health and Disease" before the Cambria County Medical Society in Johnstown recently.

## Pittsburgh

**Psittacosis Reported**—Two cases of psittacosis were reported in Springdale on May 5, according to the Pittsburgh Telegram. The disease occurred in two neighbors, aged 68 and 38.

**Society News**—Dr Charles B Huggins, Chicago, addressed the Pittsburgh Urological Association, May 1, on "Endocrine Relationship of Prostatic Carcinoma."—Dr Joseph Stokes Jr, Philadelphia, discussed "Studies on Active Immunization Against Measles" before the Pittsburgh Pediatric Society on April 24.—Among others, Drs Louis W Statti, Pittsburgh, addressed the Pittsburgh Ophthalmological Society, April 27, on "Pentothal Sodium Anesthesia in Ophthalmology" and Edmund B Spaeth, Philadelphia, treatment of chronic dacryocystitis.

## VIRGINIA

**Federal Grant to Assist in Hospital Expansion**—A grant of \$695,880 by the Federal Works Agency to King's Daughters' Hospital, Portsmouth, will finance the addition of a four story wing, providing one hundred and thirty additional beds, it is reported. The grant will also provide a new nurses' home and complete equipment.

**State Conference of Social Work**—The program of the medical and health section of the Virginia State Conference of Social Work in Richmond, April 24-25, included a morning session devoted to the recent trial of the United States versus the American Medical Association in Washington. Mr John H Lewin, special assistant, attorney general's office, and Mr Seth Richardson, counsel for the American Medical Association, presented a discussion. Mr Watson B Miller from the Federal Security Agency's Office spoke on "Federal Plan for Extending Health in Medical Services." All are of Washington, D C.

**New Dean at Medical College**—Dr Jacques P Gray, director of the Hillsdale County (Mich) department of health, Hillsdale, under the auspices of the W K Kellogg Foundation has been appointed professor of preventive and public health medicine and dean of the Medical College of Virginia, Richmond, effective July 1. Dr Lee E Sutton Jr, who has been dean at the medical school since 1932, will continue as professor of pediatrics. Dr Gray graduated at Johns Hopkins University School of Medicine, Baltimore, in 1928. At one time he served as director of public welfare of San Francisco County and lecturer in public health, University of California, Berkeley.

**Changes in Health Personnel**—Dr Daniel Hope Jr, Lawrenceville, formerly assistant health officer of the Brunswick Greenville-Mecklenburg health district, has been appointed health officer of the Alleghany-Botetourt health district with offices in Covington, succeeding Dr Wyatt E Royce, Covington, who has been transferred to the tuberculosis outpatient service of the state health department at Richmond. Dinwiddie County has joined with Sussex-Prince George counties as a health district under Dr Francis J Clements, Stony Creek, health officer.—Dr Wallace E Baker, Petersburg, has been appointed assistant epidemiologist in the division of venereal disease control of the state department of health. Dr William E Chapin, Richmond, has been named to succeed Dr F. L. E. Chapman, Richmond, in his former position of field epidemiologist for the Camp 1 area with headquarters in Petersburg.—Dr Beverly L Herday, Wytheville, has resigned as health officer of Wythe County effective April 1.

## WYOMING

**State Society Meeting in August**—At a special meeting of the council of the Wyoming State Medical Society in Cheyenne April 20, it was decided to hold the 1942 annual session in Cheyenne, August 16-18

## WASHINGTON

**Meeting of Obstetricians**—Dr David H Houston Seattle was chosen president of the Washington State Obstetrical Association at its meeting in Seattle, April 18 succeeding Dr Richard S Mitchell, Wenatchee Dr Robert H Stewart, Seattle, was named vice president and Dr Henry H Skinner, Yakima, was reelected secretary-treasurer Dr Robert D Mussey, Rochester, Minn., was the guest speaker, on "Hypertension in Pregnancy" and "Endometriosis"

## GENERAL

**Golf Prizes for Specialists**—Nine silver pitchers have been presented by members of the "old guard" in the American Medical Golfing Association to be won by players representing each specialty during the annual golf tournament at the Seaview Country Club in Atlantic City, N J, June 8 These prizes are in addition to the numerous other prizes announced in THE JOURNAL, May 2, page 47

**Russian Memberships Conferred on Americans**—The Russian Academy of Science, Moscow, has elected to honorary memberships three Americans and two Britons, the first foreigners to be so honored since the revolution, according to the New York Times, May 10 The Americans are Dr Walter B Cannon, George Higginson professor of physiology, Harvard Medical School, Boston, Ernest O Lawrence, Ph D, professor of physics and director of the Radiation Laboratory, University of California, Berkeley, and Gilbert Newton Lewis, Ph D, since 1912 professor of chemistry and dean of the college of chemistry at the University of California The Britons are Sir Henry H Dale, M D, physiologist, and John B S Haldane, F R S, professor of biometry, University College, London

**Reduction in Potency of Digitalis**—Examinations of a number of samples of each of the various pharmaceutical forms of digitalis indicate that a substantial reduction in potency will result in changing from U S P XI to U S P XII standards The exact reduction is not predictable, but data indicate that the reduction will amount to 40 per cent or more in at least half of the cases In a drug in which standardization is as important as with digitalis, a change in potency of this magnitude is of the greatest interest to the physician and the patient In a statement to manufacturers of digitalis preparations, W G Campbell, commissioner, Food and Drug Administration, suggests that during the transition period in which U S P XI and U S P XII products may both be available, conspicuous notice of the reduction in potency be given on the labels

**Committee to Direct Morale**—The American Psychiatric Association appointed a committee at its annual meeting in Boston, May 21, to present forcefully to the authorities in Washington the need for a greater use of psychiatry in the armed forces and for the maintenance of civilian morale Members of the committee are Drs Arthur H Ruggles Providence, R I, Edward A Strecker, Philadelphia and Frederick W Parsons, New York A program seeking to obtain "the emotional adjustment of the nation as a whole by teaching school children the laws of social and mental hygiene was outlined by Drs Mesrop A Tarumian, Farnhurst Del director of mental hygiene clinics of Delaware, Persis F Einfeld Wilmington, assistant director and H Edmund Bullis Wilmington executive director of the Delaware State Society for Mental Hygiene

**Special Society Elections**—Dr Eli K Marshall Jr, Baltimore, was chosen president of the American Society for Pharmacology and Experimental Therapeutics at its annual meeting recently Other officers include Drs Carl A Dragstedt, Chicago vice president Raymond N Bieter Minneapolis secretary, and Erwin E Nelson New Orleans treasurer The next annual session is planned for the first week in April in Cleveland—The American Institute of Nutrition elected the following officers at its meeting in Boston April 1 Leonard A Maynard Ph D Ithaca N Y president Howard B Lewis Ph D, Ann Arbor Mich, vice president Arthur H Smith Ph D, Detroit, secretary, Dr William H Sebrell Jr, Washington D C treasurer

**Warring of Impostor**—A middle aged man giving the name of Henry Calvin Van Dyke (or Van Dyke) has been victimizing laboratory workers, particularly biochemists and bacteriologists He pleads exhaustion of funds, asks for temporary work, accepts loans of money He claims to have a Ph D in chemistry from the University of Leyden and to have studied at Oxford and Bonn He claims to have inherited wealth from his Dutch father and Scotch mother but to have lost it in 1939, and to have served as a volunteer worker in various scientific laboratories especially in and around San Francisco Recently he has been "working" around New York and Baltimore He is about 60, is 5' 7" tall, weighs 150 pounds His clothes are good his manners excellent, his English is perfect save for a somewhat guttural accent He can converse in French, German or Dutch and has a know ledge of history, art mathematics and scientific methods His laboratory technique shows excellent training He has made claims of working with reputable men and institutions in this country, none of which have been found to be true, according to reliable reports This matter has been placed before the Federal Bureau of Investigation and the New York Police Department Should he approach physicians for funds or employment, they should notify local police authorities

**American Gynecological Society**—The sixty-seventh annual meeting of the American Gynecological Society will be held at Skytop Lodge, Skytop Pa, June 15-17, under the presidency of Dr William C Danforth, Evanston, Ill Included among the speakers will be

- Dr George W Kosmak New York The Gynecologic and Other Implications Which Relate to an Aging Female Population
- Dr John I Brewer Chicago Studies of the Human Corpus Luteum Evidence for Early Regression of the Corpus Luteum
- Dr Willard M Allen St Louis The Effect of Progesterone in Adolescent Girls and Young Women with Functional Uterine Bleeding
- Dr Edward G Waters Jersey City N J, Selective Hysterectomy for Nonmalignant Uterine Disease
- Dr Daniel G Morton San Francisco Observations on the Development of Pelvic Conformation
- Dr Kyle B Steele New York The Classification of the Obstetrical Pelvis Based on Mensuration and Morphology
- Dr Andrew C Ivy Chicago The Functional Anatomy of Labor with Special Reference to the Human
- Dr Franklin F Snyder Chicago The Experimental Production of Toxemias of Pregnancy

The annual dinner of the society will be held on Tuesday, June 16, at 8 p m

**Registration Under Harrison Narcotic Act and the Marihuana Tax Act**—On or before July 1, every physician registered under the Harrison Narcotic Act or under the Marihuana Tax Act, or under both must reregister with the collector of internal revenue of each district in which he maintains an office or a place for the treatment of patients Failure to reregister within the time allowed by law adds a penalty of 25 per cent to the annual tax payable at the time of registration and in addition makes the physician in default liable to a fine not exceeding \$2000 or to imprisonment for not exceeding five years or to both In recent years the Commissioner of Internal Revenue has given some negligent or recalcitrant physicians the choice between paying substantial sums by way of compromise in lieu of the penalties for their offenses or as an alternative accepting criminal prosecution with resultant publicity and liability to fines and possible imprisonment This was an act of grace on the part of the commissioner he might have instituted criminal prosecutions without allowing the offending physicians any choice in the matter If the course that the commissioner has adopted does not produce the desired promptness in registration he will have no recourse other than criminal prosecution to attain that result

**First Fellowship Under Lawrason Brown Fund**—Mr Henry Clark Jr Scotland Neck N C who was a student at the University of Rochester School of Medicine New York has been designated the first fellow under the Lawrason Brown Memorial Fund Mr Clark who became ill with tuberculosis at the end of his third year (1939-1940) and was treated at Trudeau Sanatorium Saranac Lake will carry on research on the influence of anesthesia on respiration in health and tuberculous patients The fund was established by friends of the late Dr Lawrason Brown to finance one or more fellowships for research in diseases of the chest The selection of the fellows preferably those who have recovered from tuberculosis is made by a committee comprising Drs Leroy U Gardner Saranac Lake Louis Hartman Baltimore Leonard R Long Philadelphia David R Lyman Willingford Conn James Woods Price Saranac Lake and William P Thompson New York The fund is managed by the Saranac Lake Society for the Control of Tuberculosis Should the society ever cease to exist the management of the fund shall be vested in the trustees of the Saranac Lake Sanatorium

first to Johns Hopkins University and then to another competent organization selected by the unanimous vote of the memorial committee. The establishment of the fund was announced late in 1940 and now stands at more than \$31,000. The original goal was set at \$50,000.

**Northwest Medical Association**—The twentieth annual session of the Pacific Northwest Medical Association will be held at the Hotel Multnomah, Portland, Ore., June 17-20. The speakers will include:

Dr. Anton J. Culson, Chicago, On Inadequate Criteria of Health, The Machinery of Appetite for Foods, What is the Matter with the American Diet, and Some Unknowns in the Physiologic Pathology of Aging.

Dr. Arlie R. Barnes, Rochester, Minn., Pulmonary Embolism, Changing Concepts of Coronary Artery Disease and Electrocardiographic Abnormalities in Various Types of Heart Disease.

Dr. Jerome W. Conn, Ann Arbor, Mich., Nature of Obesity and Its Management, Spontaneous Hypoglycemia, Changing Concepts of Diabetes Mellitus.

Dr. Elmer L. Sevringhaus, Madison, Wis., Diagnostic and Therapeutic Problems Associated with the Menopause, The Use of Pituitary Preparations in the Treatment of Dwarfism and of Sex Retardation and Survey of Endocrine Preparations in Therapy by the General Practitioner.

Dr. Warfield M. Fitor, Baltimore, The Treatment of Tetanus and the Use of Tetanus Toxoid, Treatment of Wounds Involving Soft Parts and Intestinal Antisepsis with Sulfonamides.

Dr. Frederic E. Templeton, Chicago, Mucosal Relief Technique for the Roentgenologic Examination of the Esophagus, Stomach and Duodenum, Correlation of Roentgenologic and Gastroscopic Methods in Diagnosis of Gastric Disease and Roentgenologic Aspects of Esophageal, Gastric, Duodenal and Jejunal Ulcer.

Lieut. Daniel W. Wheeler, U. S. Navy Medical Corps, Bremerton, Wash., Physiologic Aspects of War Injuries.

Lieut. Comdr. Lawrence R. Gowan, U. S. Navy Medical Corps, Bremerton, Psychiatric Aspects of Military Disabilities.

Brig. Gen. Lewis B. Hershey, U. S. Army, Washington, D. C., American Medicine and the War.

Col. Paul W. Gibson, U. S. Army Medical Corps, Vancouver, Wash., The Doctor as a Medical Officer in the Army.

## HAWAII

**New Society of Clinical Pathologists**—The Hawaii Society of Clinical Pathologists was recently organized in Honolulu with Drs. Carl F. Tessmer, Honolulu, president, and Ivin L. Tilden, Punahoa, secretary-treasurer. The first regular meeting was addressed by Dr. Eric A. Fennel, Honolulu, who discussed the development of pathology in Hawaii during the last twenty years and Drs. Isaac A. Kawasaki, Abram S. Benenson and Philip P. Green, all of Honolulu, "A Consideration of Common Diarrheal Diseases of Bacterial Origin."

## LATIN AMERICA

**Personal**—Dr. Edgar D. Adrian, professor of physiology, Cambridge University, Cambridge, England, is giving a series of lectures under the auspices of the British Council in Buenos Aires, according to *Science*.

**Urologic Meeting**—The Mexican Urological Association met in annual session in Mexico City, May 11-14. Among the speakers were Drs. Hugh H. Young, Baltimore, William F. Braasch, Rochester, Minn., and Robert Gutierrez, New York, who have been elected honorary members of the association.

## FOREIGN

**Hadassah University Pharmacological Institute**—The establishment in Palestine of a pharmacologic institute for clinical research and a pharmaceutical laboratory for the extraction of vitamins, hormones and allied substances has been announced by the Women's Zionist Organization of America, Inc., to be known as the Hadassah-University Pharmacological Institute. Scientists associated with the Hebrew University and the Rothschild-Hadassah-University Hospital, both of which are situated on Mount Scopus outside of Jerusalem, will be jointly responsible for the project. A Geiger, now head of the laboratory of general physiology of the Hebrew University, will have charge of the pharmaceutical program. The Hebrew group, which last year was granted priority space free of charge by the British War Relief Society and the British Ministry of Shipping on all vessels leaving this country for Palestine, has been sending consignments in different products to supplement shortages which have already developed. It is hoped that the new laboratory will work out methods to develop and encourage the pharmaceutical industry as far as possible with local raw materials.

### Deaths in Other Countries

**Sir Thomas Oliver, M.D.**, London, authority on industrial diseases, died on May 16 at Newcastle, aged 89. He was former president of the University of Durham College of Medicine, Newcastle, a consulting physician of the Royal Vic-

toria Infirmary, Newcastle, and former medical expert of the Dangerous Trades Committee of the Home Office. He was delegate of the Australian Commonwealth International Labor Conference at the League of Nations in 1921 and honorary president of the International Congress of Accidents and Industrial Diseases at Geneva in 1931.

## CORRECTIONS

**Professional Dentistry in American Society**—In a review of this book in *THE JOURNAL*, May 2, page 114, the second sentence in the review should not have been placed in quotations and it should have read: The period of professional awakening, 1820-1840, is discussed with respect to the establishment of medical schools and the rise of medical journalism.

**Medical Recruiting Boards**—In the list of twenty-seven medical recruiting boards published in *THE JOURNAL*, May 16, page 271, the Ohio board should have been as follows: Major H. S. Perry of the Adjutant General's Department and Capt. Clarence E. Northrup, M.C., representing the medical department. Captain Northrup was erroneously listed as on the Indiana board. The names as published in *THE JOURNAL* were taken from the *Army and Navy Journal* of May 2.

## Government Services

### Dr. Pelouze Named Consultant in Gonorrhea Program

Dr. Percy S. Pelouze, assistant professor of urology, University of Pennsylvania School of Medicine, Philadelphia, has been appointed consultant for the gonorrhea control program with the U. S. Public Health Service. His first field assignment was to the state of North Carolina.

### Annual Report of Veterans Administration

During the year ended June 30, 1941 there were 187,374 admissions of U. S. veterans to hospitals, an increase of 4 per cent over those for 1940 and the highest for any fiscal year to date, according to the annual report of the Administrator of Veterans' Affairs. The hospital load at the end of the year was 58,417 as compared with 56,841 in the previous year, an increase of about 3 per cent. The neuropsychiatric load increased 1,509 while the tuberculosis load decreased 19. At the close of the year 78.53 per cent of the U. S. veterans under hospitalization were receiving treatment for disabilities not of service origin. Of the total patient load 52,088 were World War veterans, Spanish-American War 2,992, Civil War 13, all other wars, expeditions and occupations 66 and regular establishment 2,999. Of the patients at the close of the year, 8.02 per cent were under treatment for tuberculosis, 59.14 per cent for neuropsychiatric diseases and 32.84 per cent for general medical and surgical conditions.

During the year 251,293 patients were under hospitalization of whom 246,777 were United States veterans. The total number treated represents an increase of about 55 per cent over 1940. Of the group treated 188,617 were discharged after an average of 73.8 inpatient days. Deaths in hospitals totaled 12,891.

At the end of the year the Veterans Administration was operating hospital facilities at ninety-one locations in forty-five states and the District of Columbia with a capacity of 61,849 beds, an increase of 2,212 over the number available on July 1, 1940. In addition, the administration was using 2,570 beds in other government hospitals. There were 18,747 beds set aside for domiciliary care. On completion of new construction and progress in June of this report there was a combined total of 86,171 beds of all types for beneficiaries of the Veterans Administration.

The net operating expense for all hospital and domiciliary facilities controlled by the administration totaled \$61,113,968. The per diem cost of operation for all types of cases was \$27. A total of 1,111,589 outpatient physical examinations were made and 1,176,685 outpatient treatments furnished. Two per cent of the examinations and 9 per cent of the treatments were dental.

During the year a new chest surgery center was established in the facility at Livermore, Calif., supplementing the center already in operation at Castle Point, N. Y., Queen's Legion, Texas, Tucson, Ariz., and San Fernando, Cal. A fever therapy clinic is being organized at Northport, L. I.

### LONDON

(From Our Regular Correspondent)

April 18, 1942

#### The Rations of Enemy Prisoners

A revised scale of rationing for enemy prisoners has come into force. Excepting those employed in working parties the foodstuffs issued will be limited to the quantities allowed to British troops employed on sedentary duties. Working parties will continue to receive the normal home service ration but modified to meet the taste of the nationals concerned. In working parties the Germans will get 6 ounces of meat daily and the Italians 4 ounces. But the Italians will receive 16 ounces of bread daily compared with the Germans' 10 ounces, and 16 ounces of potatoes against 13 ounces for the Germans. The Germans' ration of sausage or offal will be three issues of 4 ounces weekly, the Italians will get none. Both will receive daily 1½ ounces of margarine, 1½ ounces of bacon, 4¼ ounces of cheese, 1 ounce of jam, 2 ounces of sugar, 1⅞ ounces of coffee, 3 ounces of condensed milk and 5½ ounces of fresh vegetables. Prisoners not in working parties receive daily 2½ ounces of meat, ¾ ounce of margarine, ¼ ounce of bacon, 2⅞ ounces of cheese, 1¼ ounces of sugar, 32 ounces of potatoes and 5½ ounces of fresh vegetables. Italian prisoners will get 1¼ ounces of tobacco weekly.

#### Cross Infection in Hospital Wards

In the Section of Epidemiology of the Royal Society of Medicine a discussion on cross infection in hospital wards was opened by Dr Robert Cruickshank, who defined cross infection as infection of a patient with the causal agent of a disease other than that for which he had been admitted. This definition included both manifest and latent infection. Persons might be cross infected with other biologic types of the organism responsible for the primary infection, e.g. in streptococcal, pneumococcal and diphtheritic infections. An example was a streptococcal cross infection rate of over 50 per cent in a measles ward, in which two thirds of the patients were clinically infected and one third latently. More than 60 per cent of the complications in scarlet fever were due to cross infection. The streptococcus was the arch enemy, but staphylococcal infections in infant nurseries, outbreaks of infantile diarrhea and cross infection with the diphtheria bacillus in scarlet fever and measles wards were too frequent.

Cruickshank divided cross infection into three forms: respiratory or inhalational, intestinal or ingestion and contact or implantation. More attention should be given to the air as the vehicle for the spread of respiratory infections. For the control of cross infection the reservoirs must be attacked and the channels blocked. Sulfonamide derivatives were proving useful, and sprays might be used more frequently for the streptococcal throat. Patients should cover their coughs and sneezes with a handkerchief. Masks should be more freely worn by nurses and convalescents must not be allowed to come in contact with the sick. Infected dust was a major problem in hospital wards and should be prevented by oiling bed linen and clothes. Search for carriers had proved valuable in the control of outbreaks of Flexner and Sonne dysentery.

Dr R. H. Dobbs said that in children's wards the solution was threefold: (1) hospital design with admission cubicles, small ward units and adequate isolation accommodation; (2) alertness to detect infection in new admissions and in the ward; (3) isolation of suspected or manifest infection, bacteriologic search for carriers, passive or active immunization against measles, diphtheria and scarlet fever.

Dr N. D. Begg dealt mainly with gastroenteritis and streptococcal infections in infectious disease hospitals. In a London

hospital patients admitted with enteritis were nursed in completely separate cells, feeds were prepared in a special room and the full technic of an isolation block was used. In two years among 390 admissions there were only 3 instances of secondary infection.

#### Danger of Famine and Pestilence

A conference on scientific problems in the postwar reconstruction of peasant agriculture in Europe, arranged by the British Association for the Advancement of Science, has taken place. The chairman, Sir John Russell, director of the Rothamsted agricultural experiment station, said that the Germans as they were expelled from the occupied countries would do damage that would stagger humanity and leave behind only famine and pestilence. Diseases of malnutrition, tuberculosis, malaria and typhus would be rife. The task of reconstruction would be difficult, and large scale relief imperative. As an integral part of the relief measures, we must get the agriculture of each country going, so that food would be produced on the spot, especially milk and the protective foods necessary to save children from growing into deformed men and women. Plans could be made with more certainty than in some other directions. The peasants would need seeds, animals, food for animals, implements for cultivation, cottages, stables and other buildings for animals.

Mr Kenneth G. Brooks of the Society of Friends said that the society had centers in nearly all European countries during and after the last war. Its experience established four main principles: 1. It is impossible to separate relief from rehabilitation. 2. Short and long term policies in agriculture must run concurrently. 3. International coordination of monetary and fiscal policy is essential. 4. Personnel aid must be provided on a generous scale and must have special qualities of human sympathy as well as professional and practical qualifications.

Mr A. J. Drexel-Biddle, American ambassador accredited to the allied governments in London, presided over one session and said that Russia's 'scorched earth' policy meant not only the burning of Russian villages but the destruction of live stock, crops and all that could not be carried away. These conditions would call for large scale postwar relief and agricultural reconstruction. In Poland also reconstruction would be a serious problem. For the restoration of the crops, various types of good seeds would be required. In the reestablishment of live stock, artificial insemination, in which Russian scientists had made great advances, would play an important part. American and Canadian organizations should get ready to supply breeding stocks for live stock in Poland in the scorched earth areas of Russia and in other European countries where live stock had suffered huge losses.

#### The British Medical Students' Association

In these days, when every calling has its organization and every branch of the medical profession has one it is not strange that medical students should organize. Until April 1940 there was no organization which could claim to represent them. There was then in existence an organization of students in general, the National Union of Students, which was holding a congress. At this the first move was made to form the British Medical Students Association as a faculty subcommittee of the National Union of Students. For a year no substantial change occurred. The British Medical Students Association represented only a minority of the National Union of Students, about 30 per cent, and most were members of provincial medical schools whose universities were members of the National Union of Students. Many attempts were made to increase the membership of the British Medical Students Association but with little success until July 1941 when it approached the Medical Planning Committee of the British Medical Association which informed it that a memorandum representative of medical student opinion on reform of medical education would be welcome. The need to make this memorandum representative of

all medical schools was realized and their cooperation was sought. But for various reasons the connection with the National Union of Students proved an insuperable obstacle. An alternative organization to be fully representative of all medical schools is being formed.

The reform of medical education is the most important matter which the British Medical Students' Association has taken up. In the last ten years papers on this subject have been published in this country and in America. The most comprehensive is the final report of the American Commission on Medical Education, which was abstracted in *THE JOURNAL*, Dec 24, 1932, page 2206. Another subject is the measures taken to safeguard the health of students. They vary greatly and are excellent in most hospitals, but there are exceptions. The conditions of admission of women to medical education have been the subject of much controversy and must be faced in order that a sound solution may be reached.

### Scheme for Training the Disabled

In addition to the members of the fighting services, the merchant navy and the civil defense services disabled in the war, civilians are injured in air raids and accidents in factories. The Ministry of Labor has introduced a scheme for the resettlement in civil life of these disabled persons, including training for a new occupation when this is desirable. The winning of the war demands the full use of all available labor, and disabled men and women can make a valuable contribution to this, in some cases by entering the munitions industry.

The Ministry of Labor has arranged for its officers to get into direct touch with disabled persons while still in the hospital to ascertain individual requirements in the way of employment and to do everything possible to meet them. The matter will also be discussed with the physician or surgeon attending the disabled person. In amputation cases there will be a special report from the limb fitting surgeon at the center where the artificial limb is supplied. Many disabled will want to return to their former occupation but will not know whether changes produced by the war in industry prevent this. Others will want to know which of the industries open to them will be of most value in the war effort. Some, prevented by their disablement from resuming their former occupation, will want to know what other occupation is available.

In many cases disabled persons will require training. Two schemes are administered by the ministry: the existing training scheme for munition work and a new scheme for the special benefit of the disabled. The cost of training is paid by the ministry, and the trainees are paid wages. Foreigners disabled in the war are eligible. There is medical supervision during the training course to ensure that this is suitable to the particular disablement.

### Roentgen Examination in Pulmonary Tuberculosis

The National Association for the Prevention of Tuberculosis has issued a memorandum enjoining the greater use of radiographic methods in the discovery of tuberculosis, particularly of the symptomless cases in young apparently healthy persons. It points out that pulmonary tuberculosis begins without any warning to the patients. By the time they voluntarily come for treatment the disease is advanced and perhaps they have infected others. In the British Isles there are about a quarter of a million cases of pulmonary tuberculosis, of which about 1,500 between the ages of 15 and 50 prove fatal each month. For prevention we must more persistently try to discover early cases before they have become infectious, as this would ultimately mean the conquest of tuberculosis. The only method of detecting tuberculosis before it produces symptoms is x-ray examination of the chest. The association holds that when these facts are known public opinion will insist on this method taking the

place of older less effective methods. The ideal would be examination of every young person on leaving school and at intervals during early adult life. Entry into the various occupations or into secondary schools and colleges provides an opportunity for this examination. Under the Factory Acts the certifying surgeon examines those who enter industry under the age of 16. This should include x-ray examination. At present our tuberculosis services deal only with those who come to them because they have symptoms of tuberculosis. Earlier detection would mean a better hope of eradicating the disease.

### Soap Rationed

The latest substance to be rationed is soap. Every person's consumption per week is limited to 4 ounces of household soap, 3 ounces of toilet soap, 3 ounces of soap flakes or chips, 6 ounces of soft soap, 6 ounces of soap powder No 1 or 12 ounces of powder No 2. Shaving soap, scourers, shampoo, liquid soap and dental soap are not rationed. The decision to ration soap has been made not because there is a scarcity but to secure economy in the use of imported oils and fats and to make certain that available shipping space may be used to import edible fats. The Ministry of Food has been supplying soap manufacturers with 300,000 tons of fats yearly. Eighty-two per cent of the total soap consumption is for domestic purposes. The ministry estimates that, with rationing, 80 per cent of the present consumption can be maintained.

### The First \$50,000,000 of the Red Cross Fund

The duke of Gloucester, president of the British Red Cross Fund, stated at a meeting that the collection by the fund of its first \$50,000,000 was an encouraging achievement. Now in the third year of the fund it was hoped to add a further \$25,000,000. Mrs Churchill's Aid to Russia Red Cross Fund stood at \$7,500,000. The Red Cross would in any case have helped Russia, but it congratulated Mrs Churchill on her remarkable result. At present money is being collected weekly for the Red Cross at the following rates: workshops \$125,000, house to house \$85,000. The total weekly collections, mostly subscribed in amounts of 2 cents, amount to over \$10,000,000 annually. Owing to the spread of the war to the Far East the demands on the Red Cross must continue to expand.

### American Ambulances for the Allies

The thousandth vehicle for which the allies have to thank the British War Relief Society of America has been handed over for Russia by Mr B N Cruger. The ambulance was accepted by Mme Maiskay, wife of the Soviet ambassador. The vehicles already given or maintained by the society represent only part of its activities for the allied cause. It maintains two hundred and seventy vehicles in Britain. In the quieter days now following the heavy air raids they carry 2,500 hospital patients weekly besides performing other duties. Traveling canteens are maintained for one year by their American donors. Some of the thousand vehicles are of unusual types. One is a mobile bathroom, given to the people of Plymouth for use in their evacuation area.

### Heroism of a Woman Physician

The award of MBE has been made to Dr Adaline Nancy Miller, ship surgeon. Her ship was approached by a raider, which opened fire at long range. The defensive armament replied, but a shell put the main gun out of action and heavy structural damage was done. As the speed was less than that of the enemy, the captain gave orders to abandon ship. A signal to this effect was made to the enemy, but he continued to shell and holed many of the lifeboats. He then sank the ship with gunfire and made off. During the action Dr Miller, with feet calm, attended to the wounded and dying. She continued her work after the company had taken to the lifeboats.

## BRASIL

(From Our Regular Correspondent)

March 31, 1942

### Inguinal Hernia from the Legal Point of View

According to a paper by Dr. Carlos Roberto de Barros, inguinal hernia usually is not a suitable fit since it is not cured but is merely treated, and it is often noticed of months and years. From the legal point of view, inguinal hernia as an occupational disease and accidental hernia are well defined entities. The patients are prone to attribute any hernia to some violent incident during their work, while the physicians are in the habit of regarding hernia as a congenital disease. According to the theory of hernia as an occupational disease, legal textbooks do not take into consideration professional conditions concerning hernia as an occupational disease, but compensation has to be examined for accurate evaluation of the degree of incapacitation. Chiefly the differentiation between inguinal hernia as a professional disease and as an occupational condition seems to be impossible, even microscopic examination of the protruded hernia sac cannot be an important method of differentiation being of value only in proving that the patient has or has not an accidental hernia. Jurists emphasize that although he can be forced to have a hernia operation, but a worker who has broken a bone is obliged to submit to adequate treatment, surgical or surgical. Dr. Roberto does not believe a man who has an occupational hernia should not have to submit to surgical treatment. The latter should be obligatory and an indemnity should be paid only in those rare cases in which permanent partial incapacity results. However, inguinal hernia is among the conditions for which there is indemnification and the worker chooses between operation or indemnification. This is not fair. The surgical treatment for hernia should be compulsory as a benefit to the employee and the worker. Only permanent partial incapacity resulting from surgical treatment would be subject to compensation, in the same way as the sequelae of amputated fracture.

### Births and Deaths Among Negroes

There seems to be a decrease in the number of Negroes in Brazil. The following numbers refer to births and deaths in 1939 in the state of São Paulo, the population of which is estimated at 7,200,000 inhabitants:

| Race   | Births  | Deaths |
|--------|---------|--------|
| White  | 97,390  | 9,476  |
| Negro  | 39,167  | 10,506 |
| Yellow | 9,500   | 1,477  |
| Total  | 146,057 | 21,459 |

Rubens de Amaral, who has made statistical studies in all regions of the state of São Paulo, said that the mortality is higher among the Negroes in populous centers than it is in the country. He advises that the Negroes should live only in the country and he suggests several measures that would tend to improve their standard of living.

### Vital Statistics in São Paulo

During 1941, 19,413 people died in the city of São Paulo, of whom 10,469 were males and 8,944 females. Cancer caused 1,190 deaths, tuberculosis 1,011, pneumonia 1,021, heart disease 1,824 and intestinal troubles 1,020. In the same period, 1,333 children (1,781 boys and 1,074 girls) were born and 2,312 marriages were registered. Among the races, the deaths were as follows:

| Race    | Deaths | Births |
|---------|--------|--------|
| White   | 1,882  | 1,077  |
| Mulatto | 1,122  | 1,077  |
| Negro   | 1,077  | 1,077  |
| Yellow  | 1,077  | 1,077  |
| Total   | 5,163  | 4,331  |

### Personal

Dr. Fernando Lazzarini, professor of surgery in the São Paulo Faculty of Medicine, died last night at 8:15 after a long illness, having been ill for several days after performing a hysterectomy for uterine cancer.

## MEXICO CITY

### Barter System for Workers

An act has been signed by the president of the republic and the minister of labor according to which all employees are obliged to provide sanitary examinations for their workers. But it will be free and the law fixes several terms to contract the different types of diseases among employees and to build new ones and besides different penalties for negligence to such regulations.

### National Academy of Surgery

The National Academy of Surgery held its first session of the year on January 30 in the National Academy of Sciences in the School of Medicine. The session was presided over by Dr. Gustavo Echeverría, minister of education. Dr. Aquilino Talamo, president of the Academy of Surgery, Leticia de la Cruz, a doctor in the University of Mexico, Dr. José Torres, director of the academy and Dr. Joaquín Cárdenas, executive secretary of the academy.

### Control of Chemicals by the Department of Economics

In February the Department of Economics served a decree requiring all manufacturers and dealers to send within fifteen days a manifest of their stock of acetone, ammonia, aniline oil, carbon tetrachloride, ether, acid, copper sulfate, pyrophosphoric, potassium salts, sulfuric acid, methyl alcohol and several other chemicals, dyes and pigments. Manufacturers are ordered to use their stock only in their own factories. Exportation is forbidden as well as raising of prices. The Union of Drug Stores and chemical laboratories complained in a recent meeting that many dealers have raised unduly the price of most medicines and chemicals.

## Marriages

JAMES PATTERSON SMITH, 3000 10th St. N.W., to Miss Margaret Elizabeth Smith of Earthquake, Pa. February 21.

JOHN J. JONES, 1000 1st St. N.W., to Miss Katherine Louise Jones of Washington, Pa. March 1.

ALBERT ROBERTSON, 1000 1st St. N.W., to Miss Ann (Betty) Lillian of Orange, Pa. March 1.

WILLIAM MARTIN, 1000 1st St. N.W., to Miss Anna Marie of Birmingham, Pa. March 1.

EDWARD J. SMITH, 1000 1st St. N.W., to Miss Jane (Coke) Smith of Atlanta, Pa. April 1.

CAROL ROBERTSON, 1000 1st St. N.W., to Miss Anna Marie of Orange, Pa. April 1.

JOHN J. JONES, 1000 1st St. N.W., to Miss Anna Marie of Orange, Pa. April 1.

ALBERT ROBERTSON, 1000 1st St. N.W., to Miss Anna Marie of Orange, Pa. April 1.

WILLIAM MARTIN, 1000 1st St. N.W., to Miss Anna Marie of Birmingham, Pa. March 1.

EDWARD J. SMITH, 1000 1st St. N.W., to Miss Jane (Coke) Smith of Atlanta, Pa. April 1.

CAROL ROBERTSON, 1000 1st St. N.W., to Miss Anna Marie of Orange, Pa. April 1.

JOHN J. JONES, 1000 1st St. N.W., to Miss Anna Marie of Orange, Pa. April 1.

ALBERT ROBERTSON, 1000 1st St. N.W., to Miss Anna Marie of Orange, Pa. April 1.

WILLIAM MARTIN, 1000 1st St. N.W., to Miss Anna Marie of Birmingham, Pa. March 1.

EDWARD J. SMITH, 1000 1st St. N.W., to Miss Jane (Coke) Smith of Atlanta, Pa. April 1.

## Deaths

**James Dowling Trask** \* associate professor of pediatrics at the Yale University School of Medicine, New Haven, Conn., died, May 24, in the Albert Merritt Billings Hospital, Chicago, of septicaemia and acute peritonitis, aged 51. Dr Trask was born in Astoria, L I, N Y, Aug 21, 1890. He graduated from the Cornell University Medical College, New York, in 1917, and was an intern at the Bellevue Hospital, New York. He served during World War I from May 1918 to December 1919. He was assistant resident physician at the Hospital of the Rockefeller Institute for Medical Research, New York, from 1919 until 1921, when he joined the faculty at Yale University School of Medicine as an instructor in medicine. In 1925 he was made an assistant professor of medicine and in 1927 an associate professor of pediatrics. Since 1927 he had been an associate attending pediatrician at the New Haven Hospital and dispensary. In 1939 he was appointed a commissioner of the city board of health. He was a member of the American Pediatric Society, New England Pediatric Society, Association of American Physicians, American Society for Clinical Investigation, American Clinical and Climatological Association and the Society of American Bacteriologists. He was also a member of the American Board of Pediatrics. In 1931 he was a member of the original Yale Poliomyelitis Commission to fight infantile paralysis after an epidemic of the disease had swept through Connecticut. At the meeting of the American College of Physicians in April 1942 he received jointly with Dr John R. Paul the John Phillips Memorial Medal. Dr Trask was a nationally known investigator in the field of infantile paralysis and during the last month was working in Army posts in the Chicago area on problems of hemolytic streptococcus infection as a member of the Commission on Hemolytic Streptococcal Infections of the Board for the Investigation and Control of Influenza and Other Epidemic Diseases in the Army, under an appointment as consultant to the Secretary of War.

**Julius P Dworetzky** \* Liberty, N Y, Long Island College Hospital, Brooklyn, 1910, member of the American Laryngological Rhinological and Otolological Society and the American College of Chest Physicians, fellow of the American College of Physicians, member of the American Board of Internal Medicine, Inc, and the American Board of Otolaryngology, served during World War I as a captain with the American Red Cross and with the Rockefeller Commission for the control of tuberculosis in France, director of medicine and visiting physician, Municipal Sanatorium, Otisville, visiting physician, Maimonides Hospital, consulting physician, Ulster County Tuberculosis Hospital (Kingston), Elizabeth A Horton Memorial Hospital (Middletown), St Francis Hospital (Port Jervis) and St Clare's Hospital (New York), medical examiner, Veterans Administration, aged 55, died, April 20, of brain tumor.

**Philip Allen Halper** \* Chicago, University of Minnesota Medical School, Minneapolis, 1923, member of the American Academy of Ophthalmology and Otolaryngology, fellow of the American College of Surgeons, member of the American Board of Ophthalmology and the American Board of Otolaryngology, formerly instructor in otolaryngology, associate in laryngology, rhinology and otology and associate in ophthalmology at the University of Illinois College of Medicine, assistant city and county physician, St Paul, 1924-1925, associate ophthalmologist, Illinois Eye and Ear Infirmary, attending ophthalmologist, Michael Reese Hospital and the Mandel Clinic, on the visiting staff of the Grant Hospital, associate editor of *Cyclopedia of Medicine*, aged 44, died, April 21, in Palm Springs, Calif, of hypertension.

**Thomas Henry Culhane** \* Rockford, Ill, Rush Medical College, Chicago, 1890, past president of the Winnebago County Medical Society, formerly vice president of the Illinois State Medical Society, fellow of the American College of Surgeons, on the staffs of the Rockford and Winnebago County hospitals, for many years member and at one time president of the school board, aged 73, died, April 14, in Rochester, Minn.

**Andrew Merriman Young Jr**, Oklahoma City, Vanderbilt University School of Medicine, Nashville, Tenn, 1909, served during World War I, at one time served as assistant surgeon in the U S Public Health Service, a former director of the state venereal disease bureau, aged 55, died, March 18, of heart disease at Kerrville, Texas.

**Bernice Turner Wright** \* Memphis, Tenn, University of Tennessee College of Medicine, Memphis, 1927, fellow of the American College of Surgeons, on the staff of the Vet-

erans Administration Facility, aged 39, died in March at the Baptist Memorial Hospital of an injury received in an auto mobile accident.

**Samuel Edward Sibley** \* Sioux City, Iowa, State University of Iowa College of Medicine, Iowa City, 1893, fellow of the American College of Surgeons, past president of the Woodbury County Medical Society, on the staffs of St Vincent's and Methodist hospitals, aged 72, died, March 18, of heart disease.

**Sidney L Feldstein** \* Harrisburg, Pa, Medico Chirurgical College of Philadelphia, 1902, formerly on the staffs of the Jewish and Stetson hospitals, Philadelphia, director of the x-ray service of the state department of health, aged 61, died, April 27, in the Jefferson Hospital, Philadelphia, of cerebral hemorrhage.

**George Wyckoff Cummins** \* Belvidere, N J, College of Physicians and Surgeons, medical department of Columbia College, New York, 1890, for many years county physician, member of the city board of health and board of education, aged 77, died, April 17, in the Easton (Pa) Hospital.

**Roscoe C Field**, Sheridan, Ore, University of Oregon Medical School, Portland, 1905, University of Louisville (Ky) Medical Department, 1910, for many years city councilman, member of the school board and mayor, aged 63, died, April 6 in a hospital at Portland of pneumonia and meningitis.

**Clarence Crane**, Fernbridge, Calif, Boston University School of Medicine, 1900, formerly assistant professor of surgery at his alma mater, fellow of the American College of Surgeons, at one time on the staff of the Massachusetts Memorial Hospitals, Boston, aged 70, died, April 13.

**Wilbur Curtis Hunsucker**, Bennettsville, S C, Medical College of the State of South Carolina, Charleston, 1934, member of the South Carolina Medical Association, on the staff of the Marlboro County General Hospital, aged 31, died, April 2, of cerebral hemorrhage.

**Joseph Albert Gregory**, Buffalo, University of Buffalo School of Medicine, 1908, member of the Medical Society of the State of New York, for many years a member of the board of health and a school inspector, aged 58, died, April 7, of carcinoma of the esophagus.

**Archibald Wallace Dunn** \* New York, University of Pennsylvania School of Medicine, Philadelphia, 1912, fellow of the American College of Surgeons, served during World War I, aged 59, died, April 29, in the Lenox Hill Hospital of cerebral hemorrhage.

**Robert Burnside Dawson**, Smiths Ferry, Pa, Western Reserve University Medical Department, Cleveland, 1893, member of the Medical Society of the State of Pennsylvania, aged 78, died, April 17, in the City Hospital, East Liverpool, Ohio, of uremia.

**Wilton F Blackford**, Louisville, Ky, Kentucky School of Medicine, Louisville, 1901, medical director of the Commonwealth Life Insurance Company, aged 69, died, April 2, in the Kentucky Baptist Hospital of carcinomatosis with obstruction of the intestine.

**Lynn J Tuttle**, Douglas, Ariz, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1902, fellow of the American College of Surgeons, for many years mayor of Douglas, aged 72, died, March 19, of coronary occlusion.

**Seth De Blois**, Newport, R I, University of Maryland School of Medicine, Baltimore, 1905, formerly county medical examiner, aged 59, president of the medical staff of the Newport Hospital, where he died, April 26, of coronary thrombosis.

**David Erastus Peek**, Six Mile, S C, Emory University School of Medicine, Atlanta, Ga, 1918, member of the South Carolina Medical Association, served during World War I, owner of a hospital bearing his name, aged 51, died, March 16.

**M Russell Wilcox**, Los Angeles, University of Minnesota College of Medicine and Surgery, Minneapolis, 1897, formerly assistant professor of physiology at his alma mater, member of the California Medical Association, aged 73, died March 25.

**John Tinkler** \* Buffalo, University of Buffalo School of Medicine, 1907, formerly instructor in anatomy at his alma mater, aged 62, died, March 9, in the Buffalo General Hospital of gastric ulcer and massive gastric hemorrhage.

**John Riegelman**, Mamaroneck, N Y, Bellevue Hospital Medical College, New York, 1894, formerly coroner's physician and assistant medical examiner in the Bronx, died, March 4, in the United Hospital, Port Chester.

Samuel Kendig Wallace @ Baltimore Johns Hopkins University School of Medicine Baltimore 1927 aged 40 died, March 3, in the Johns Hopkins Hospital of massive hemorrhage due to carcinoma of the transverse colon

Sigfrid J Cheleen, Fergus Falls Minn University of Minnesota College of Medicine and Surgery, Minneapolis, 1906, formerly on the staff of the Swedish Hospital, Minneapolis, aged 68 died April 1 of coronary occlusion

Russell Herbert Andrew @ Massena, N Y McGill University Faculty of Medicine Montreal Que, Canada 1935 aged 32 died April 28 in the Potsdam (N Y) Hospital of injuries received in an automobile accident

Henry Shelby Van Cleave, Burkburnett Texas University of the South Medical Department Sewanee Tenn 1898 formerly health officer of Burkburnett aged 78, died, March 5 of uremia in a hospital at Fort Worth

Andrew Fremont Wagner @ Los Angeles University of Pennsylvania Department of Medicine, Philadelphia, 1899 for many years autopsy surgeon for Los Angeles County, aged 74 died March 28 of arteriosclerosis

Charles Reiter @ New York Hahnemann Medical College and Hospital of Philadelphia 1937, was called to active duty May 23 1941 as a lieutenant (j g) medical corps U S Naval Reserve aged 29, was killed on the destroyer U S S *Trurton* which was wrecked in a storm on the coast of Newfoundland February 18

Inez Louise Clarke, Cambridge, Mass, Tufts College Medical School Boston 1904 member of the Massachusetts Medical Society aged 73 was found dead March 7 presumably of cerebral hemorrhage

Daniel Matthews Carter, Madison Ga Atlanta College of Physicians and Surgeons, 1912 member of the Medical Association of Georgia past president of the county board of education, aged 60 died, April 11

Burt Davis Harrington @ Brooklyn, Long Island College Hospital Brooklyn 1896 fellow of the American College of Surgeons, president of the board of directors of the Midwood Hospital, aged 68, died April 15

William James Dobbie, Toronto, Ont, Canada University of Toronto Faculty of Medicine 1905, for many years on the staff of the Toronto Hospital for Consumptives, Weston aged 69 died April 20

William Robert Haynie, West Memphis Ark Memphis (Tenn) Hospital Medical College 1895 served during World War I, formerly member of the state legislature aged 79 died April 12

Edward Parker Moser, San Francisco, University Medical College of Kansas City Mo 1903 Rush Medical College Chicago, 1910 aged 70, died, March 13, of arteriosclerosis and heart disease

Persons Walton Wing, Canaan N H Long Island College Hospital Brooklyn 1902 served during World War I aged 64 died March 20, in Orlando Fla, of coronary occlusion

Theodore Burton Ackerly, Glastonbury Conn, Long Island College Hospital Brooklyn 1897 formerly health officer of New Hartford aged 68 died April 15 of coronary occlusion

Monroe Holben Sollday @ Taylorville Ill Jefferson Medical College of Philadelphia 1901 on the staff of St Vincent's Hospital aged 68 died suddenly March 28 of coronary occlusion

Robert Ophenalia Currey, Chattanooga Tenn University of Tennessee College of Medicine Memphis 1912 member of the Tennessee State Medical Association aged 60, died April 26

Willard Parker Beach, New York College of Physicians and Surgeons medical department of Columbia College New York 1881 aged 82, died April 18 of congestive heart disease

Johan Alfred Rundstrom, Torsebro, Sweden, Karolinska Mediko-Kirurgiska Institutet, Stockholm, Sweden, 1892 formerly a practitioner in Chicago, aged 80, died, March 27

Jeremiah M Lindsey, Ranburne, Ala, Chattanooga (Tenn) Medical College, 1897, member of the Medical Association of the State of Alabama, aged 73, died March 1

Charles Leicester Rybke @ Portland Ore, University of Oregon Medical School, Portland 1909, on the staff of the Good Samaritan Hospital, aged 61, died, March 19

Jacob R Welch, Spencerville, Ohio, Fort Wayne (Ind) College of Medicine, 1882, member of the Ohio State Medical Association, bank president, aged 82, died in March

Harvey Reyburn Glenn @ Cochranville, Pa, Medico-Chirurgical College of Philadelphia, 1906, aged 57, died March 19 in the Lancaster (Pa) General Hospital

Lawrence Chamberlain Grosh Jr @ Toledo, Ohio, Johns Hopkins University School of Medicine, Baltimore 1930, aged 37 died April 17, of a self-inflicted bullet wound

John Franklin Jones, Le Roy, Ill, Colorado School of Medicine Boulder 1895 served during the Spanish-American War and World War I, aged 81, died March 16

Daniel Bluford Stough, Vinita Okla, Kentucky School of Medicine Louisville, 1887 member of the Oklahoma State Medical Association, aged 85, died March 19

Linton Turner @ Philadelphia University of Pennsylvania Department of Medicine Philadelphia 1903 on the staff of the Memorial Hospital, aged 63, died March 15

David D Wickson, Toronto Ont, Canada, Trinity Medical College Toronto, 1893, aged 71, on the staff of the Toronto Western Hospital where he died March 16

Louis Neuwelt, New York Columbia University College of Physicians and Surgeons, New York 1905 aged 60 died, March 13 in the Jewish Memorial Hospital

William Robert Shortridge, Flasher N D, Keokuk (Iowa) Medical College, 1898 aged 74 died March 16 in a hospital at Bismarck of intestinal obstruction

Charles Anthony Squires, Plainfield N J Cornell University Medical College, New York 1904 served during World War I aged 64 died March 21

John Wallace Henderson, Kennedy, N Y, Cleveland Homeopathic Medical College 1899 veteran of the Spanish-American War aged 67 died March 30

John Nathan Eisman, Cincinnati Harvard Medical School Boston 1938 aged 30, was found dead April 27, of an overdose of sleeping tablets self administered

Duncan Smith, Fingal Ont Canada University of Toronto Faculty of Medicine and the Western University Faculty of Medicine London 1890 died March 26

Melville F Boulden @ Frankfort Ind Illinois Medical College Chicago 1903 aged 72 on the staff of the Clinton County Hospital where he died April 7

John Ellsworth Witham, Waverlyville Ohio Miami Medical College Cincinnati 1889 aged 79 died March 11 in Venia of chronic myocarditis

Henry Philip Diekmeier @ Cincinnati Miami Medical College Cincinnati 1895 aged 70, died, April 2 of nephritis and dilatation of the heart

Paul Burmaster, Orlando Fla. Hahnemann Medical College and Hospital Chicago 1895 aged 74 died February 15 of coronary sclerosis

John Albert Riley, Alameda Calif California Medical College San Francisco 1900 aged 76 died March 28 of angina pectoris

John Ernst Barnstein, Manitowish Wisconsin Medical College 1897 also a pharmacist aged 89 died April 20 of myocarditis

### CEASE AND DESIST ORDERS

#### Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission, in helping to protect the public against misrepresentation or fraud in the medical as well as other fields, has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food, Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the labels of medicine or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order, in which the individual or company cited is ordered to cease and desist from practices which have been declared objectionable. Abstracts of some of the orders issued during 1941 follow.

**A B C Gauzband**—This was advertised by the American Bandage Corporation, Chicago, as being "medicated with an antiseptic and germicidal material rendering it self sterilizing." This, according to the company, was the result of "a secret process used exclusively by the manufacturer," and the bandage was further claimed to remain sterile even after it is removed from the package. The Federal Trade Commission declared that these claims were untrue and in September 1941 ordered the promoters of the A B C Gauzband to discontinue them.

**Clairol**—This hair coloring is put out by Joan Gelb, Morris Gelb and Leon A. Spilo, formerly of New York, who operate under the title Clairol, Incorporated with headquarters at Stamford, Conn. There are two Clairol products—the "Instant" and the "Progressive." The "Instant" was found some years ago by the American Medical Association's chemists to belong to the aniline derivative type of hair dyes, after reports of inflammation of the skin following its use had been received. The "Progressive" Clairol apparently was at first only a simple tint but seems to have had some aniline substance later added to it. In October 1941 the Federal Trade Commission ordered Joan and Morris Gelb and Leon A. Spilo to cease representing that their preparations are not hair dyes, that they recondition the hair or restore its natural or youthful color or that the results obtained are permanent, that the products supply nourishment to the hair, that they are made or compounded in France, that Instant Clairol is safe to use and that the number of treatments of their preparations used by the public is greater than is the fact.

**Copinol**—This product, also known as "Copinol Nasal Medicine," is put out by a Robert E. Overell of Los Angeles, who does business as the Copinol Company. In September 1941 the Federal Trade Commission ordered Overell to cease representing that his product is a cure or remedy for head colds, catarrh, choked nose and throat or sinus congestion, or has any value in treating such conditions beyond furnishing temporary relief to congested mucous membrane or will rid the nose and throat of, or protect the nose from, germ-laden mucus, instantly clear the head or afford quicker and more lasting relief than similar preparations. Overell also was ordered to discontinue any advertisements which failed to reveal that Copinol should not be used by persons suffering from heart trouble, high blood pressure, diabetes or thyroid disorders or that the use of his mixture over a long period may produce prolonged nasal constriction resulting in tissue damage from anoxemia, provided, however, that if the label of the preparation contains a warning of the potential dangers in its use, such advertisements need contain only the cautionary statement "Caution, use only only as directed on the label." THE JOURNAL, Aug. 17, 1935, page 528, contained an abstract of an action brought by the Food and Drug Administration against the Copinol Company of Los Angeles for making fraudulent claims on the labels which represented Copinol as a remedy for catarrh, hay fever, sinus trouble and some other things. In the same connection the government chemists had reported that Copinol consisted essentially of mineral oil, with a trace of an alkaloid such as berberine, and perfume.

**Duncan's Ozon**—The Ozon Chemical Company, Inc., trading as Duncan Chemical Company, St. Louis, was ordered by the Federal Trade Commission in September 1941 to discontinue the following misrepresentations in the sale of this product: that it is a cure or remedy or has any value in the treatment of sore throat, poison ivy, athlete's foot, colds or coughs or affords any benefit in the treatment of coughs beyond such comfort as it offers through its expectorant properties. THE JOURNAL, Aug. 26, 1933, page 725, reported a case in which a shipment of Duncan's Ozon was declared to violate the National Food and Drugs

Act because the labels falsely represented it as a remedy for rheumatism, kidney and bladder disorders, indigestion, pyorrhea and some other things. Government chemists at that time reported that it consisted essentially of pine oil.

**"Dupree" and "Dr. Gordon's" Nostrums**—Ben Gordon and Louis Gordon, trading as Bengor Products Company and Golf Products Company, New York, put out two products, one known as "Dupree Pills" and "Dr. Gordon's Single Strength Pills" and the other as "Dupree Pills Double Strength" and "Dr. Gordon's Double Strength Pills." In July 1941 the Federal Trade Commission reported that the single strength product contains, among other ingredients, extracts of cotton root bark and black hellebore and the double strength pills, ergotin. The Commission ordered the Gordons to cease disseminating any advertisements that represent these products as safe and effective treatments for amenorrhea and dysmenorrhea or that fail to reveal that the use of them may result in gastrointestinal disturbances leading to other serious ailments. In September 1939 the Commission had issued a similar order against Robert C. Oberlin, trading as Research Products Company, Cleveland, which was distributing these preparations.

**Helena Rubinstein Products**—Four of these, the "Town and Country Face Powder," "Eye Lash Grower Cream," "Eye Lash Cream and Darkener" and "Egg Complexion Soap," were advertised by Helena Rubinstein, Inc., New York, under exaggerated, false and misleading representations, according to the Federal Trade Commission. In July 1941 the Commission ordered the Rubinstein concern to discontinue such misrepresentations as that its face powder is, among other things, "proof against drying of the skin," "enlarging the pores," "the onslaughts of weather," that the "eyelash grower" is intended for "lovely long lashes," that the eyelash cream and darkener "makes the lashes dark and silky," or "prevents them from breaking" and that the egg complexion soap "purifies the skin" and "is made of eggs and soothing oils."

**Hy Phen**—In June 1937 Bradley's Laboratory, Inc., of Matoaka, W. Va., signed a stipulation with the Federal Trade Commission that it would cease representing that its "Hy Phen Tablets" relieve all types of pain and headache, are safe in all instances and constitute a competent treatment for colds. The concern also agreed to drop the words "laboratory" and "manufacturers." In July 1941 the Commission ordered Hy Phen Corporation, Matoaka, W. Va., successor to Bradley's Laboratory, Inc. to discontinue the following misrepresentations in its advertising: that Hy Phen will prevent or cure colds or is anything other than an analgesic giving temporary relief from painful symptoms, that it is superior to other products of its type or has any therapeutic value in treating such conditions as migraine headaches, infectious diseases, headaches due to infection, pains caused by abscessed teeth or by pressure on nerves, or that its use is entirely free from danger. In fact, the Commission reported that the product contains acetophenetidin, caffeine and hyoscyamus.

**Improved White Ribbon Remedy**—This product of the Gates Medicine Co., Inc., Charleston, W. Va., was known as "White Ribbon Remedy" prior to January 1940. The Federal Trade Commission reported in August 1941 that as the original preparation, White Ribbon Remedy contained tartar emetic it would not be a safe or reliable remedy for the liquor habit, that in the product as sold under the newer and longer name, tartar emetic was eliminated and there were substituted in each box 2,160 international units of thiamin chloride (vitamin B<sub>1</sub>) with sugar of milk as a carrying body, and no other ingredient. The Commission's findings were that, though the new product may contribute a negligible portion of normal human vitamin requirements, it is not effective as a liquor habit cure and the Commission thereupon issued an order against the Gates Medicine Company, Inc., to cease representing it as such a cure and to discontinue any advertising which fails to reveal that the use of the preparation may cause depression of the cardiovascular system, chronic irritation of the stomach and intestinal tract, nausea and failure to eat and get the proper amount of food minerals and vitamins necessary to maintain health.

**Jacks or Jacque**—This product, put out by Lambert Agin, trading as Jacks Chemical Company and Jacque Chemical Company, Pleasant Ridge Station, Cincinnati, was reported by government chemists to be nothing more than a diluted aqueous solution of nitric, hydrochloric and acetic acids, approximately 10 per cent in strength. The Federal Trade Commission in August 1941 declared that the product is wholly incapable of effecting any of the results claimed for it in the treatment of the conditions designated, and ordered Agin to cease representing it as a cure or remedy for gall, kidney and bladder stones, diabetes, rheumatism, swollen limbs, hives, excess acid and excess uric acid.

**"Kemico" Products**—These are put out by one F. W. Johnson trading as Kemico Park Ridge, Ill. In August 1941 Johnson was ordered by the Federal Trade Commission to cease misrepresenting in his advertisements the alleged effectiveness of preparations compounded from the formulas: (1) for certain skin preparations, such formulas being known as "Greaseless Massage Cream," "Lemon Greaseless Cream," "Pine Oil Balm," and "Debest Skin Treatment"; (2) for the hair, such formulas being known as "Hair Lay Cream" and "Dandruff Remedy"; (3) for catarrh, colds and similar ailments, the formulas being known as "Catarrh Cream," "Vapor Inhalant," "Nasal Jelly," "Pine Oil Nasal Spray," and "Menthol and Camphor Nasal Spray"; and (4) for the teeth, such formulas being known as "Teeth Whitener Formula A" and "Formula B." Specifically Johnson was ordered to cease representing, through the use of the words "remedy" or similar terms, that the mixture compounded from the "Dandruff Remedy" formula will cure dandruff or have any other effect, except giving certain temporary relief, and that the preparations compounded from his "Teeth Whitener Formula A," "Pine Oil Nasal Spray," "Menthol and Camphor Nasal Spray" and "Nose Inhalant" are safe to use.

**Madame Bea's Capsules**—That there are a safe and effective treatment for delayed unnatural or suppressed menstruation is a misrepresentation that the Federal Trade Commission in October 1941 ordered David L. Silver and O. C. Cowles trading as Mrs. C. R. Rye Drugs Beckley, W. Va. to discontinue in their advertising. They were also ordered to cease disseminating any advertisements that failed to reveal that the use of the product may cause gastrointestinal disturbances, excessive congestion and hemorrhage of the pelvic organs and in cases of pregnancy may result in uterine infection and blood poisoning.

**Marrills**—This was put out as a weight reducer by one I. Burman trading as Burtley Company, New York. Burman, according to the Federal Trade Commission, represented that by coating the body with a film of Marrills the pores of the skin would be closed and could not take in oxygen, that the body would then undertake to supply this lack of oxygen from the system and that the result of the pouring out of perspiration and burning up of fat would reduce body weight. The Commission found this theory to be false and in July 1941 ordered Burman to discontinue the foregoing misrepresentations as well as the implication that his product was compounded by one of the world's leading cosmetic scientists.

**Martha Beasley's Compound Formula No. 2 and No. 3**—These were advertised by J. V. Cordes and Mrs. J. H. Cordes doing business as Martha Beasley Associates, Detroit, and represented as safe and effective treatments for delayed menstruation and as being recommended by physicians generally. The Federal Trade Commission, however, found that they contained dangerous drugs which might produce serious results if taken in the doses recommended. In September 1941 the Commission ordered the promoters to discontinue the foregoing representations and to cease disseminating advertisements which failed to reveal that the use of the products may cause gastrointestinal disturbances and excessive congestion and hemorrhage of the pelvic organs and in case of pregnancy, bring about uterine infection and blood poisoning.

**Perfect Voice Institute**—This Chicago concern was said to have had for its chief officers a Eugene Feuchtinger, Walter A. Jordan and Mary E. Murphy. The institute promoted a correspondence course in voice development which according to the Federal Trade Commission consisted of approximately thirty lessons with which were furnished mechanical aids including a mirror, flash light, pitch pipe, tongue supports and depressors, a tape measure and a mouth gauge. In September 1941 the Commission ordered the Perfect Voice Institute and its officers to cease and desist from representing that the development and control of the muscles of the tongue or the use of their course of instruction has any beneficial effect on the voice other than to make it louder or stronger or representing that by use of their course of instruction physical defects of the vocal organs may be corrected or stammering overcome.

**Pond's New Skin Vitamin Creams and Danya Lotion**—The creams in question consist of a liquefying cream, a cold cream and a vanishing cream. Since 1938 according to the Federal Trade Commission each of these products of the Pond's Extract Company, New York, has contained 3,100 vitamin A units and 165 vitamin D units and the advertising has described the vitamin A as a skin vitamin and as having the effect of nourishing the skin. The lotion was represented as storing up the skin vitamin in the hands of the user. The creams were further represented to penetrate to the under skin of the user, stir it to vigorous action and keep it active and also apparently to wipe away lines and blemishes and freshen and smooth the skin. The Commission found that the small amount of vitamin A in the creams is in contact with the skin for so short a time that no effective absorption can take place and even if it could and were carried into the blood stream the effect would be systemic and not local. Accordingly in September 1941 the Commission ordered the Pond concern to discontinue the foregoing misrepresentations.

**Rosse Rheuma Tabs**—In August 1941 the Federal Trade Commission ordered Edward C. Rosse trading as Rosse Products Company, Chicago, to discontinue false and misleading representations in the promotion of this product such as that it is a cure or remedy for rheumatism, rheumatic pains or sensitive joints or furnishes anything beyond temporary relief from the symptoms of pain.

**Spencer System**—Under this name John L. Shea, William J. Hagerty, Jean G. Mitchie and Glenda S. Hills, all of Boston, sold courses in which they instructed students in the design and fabrication of arch supports and foot exercisers. In September 1941 the Federal Trade Commission ordered the Spencer System and the persons named to cease and desist from the following misrepresentations: that their courses of instruction or any substantially similar ones will equip anyone with learning and proficiency adequate to diagnose and determine whether foot troubles require surgical treatment and to treat effectively nonsurgical foot troubles or any foot disorders whatever.

**Sterling Diathermy Machine**—According to the findings of the Federal Trade Commission this device consisted principally of a high frequency generator encased in a portable wooden cabinet and was applied to the patient by placing the condenser pads in such position that the power might pass between them through the affected area at stated intervals for varying periods of time. The Commission found further that the use of this device for self treatment by the unskilled layman would not accomplish the results claimed by its promoters and that it was not a safe, scientific and effective method for the relief, cure or treatment of self diagnosed ailments of the human body. In September 1941 the Commission ordered Nolan B. Stadler, trading as the Sterling Appliance Company, Los Angeles, to cease making false and exaggerated claims for his mechanism and to discontinue any advertisements which failed to reveal that the unsupervised use of the device by persons not skilled in the diagnosis, analysis and methods of treatment of disease may result in serious and irreparable injury to health.

**Thermalaid**—This is an electrical device promoted by Thermalaid Method Inc., Steubenville, Ohio. In July 1936 when the device was being put out under the name of the Electro Thermal Company of Steubenville, the Federal Trade Commission ordered this concern to cease representing that the use of the device constitutes a competent treatment or cure for prostatitis, hypertrophy or any other ailment and that those who use it may expect immediate relief from backache, pains, worry and debilities due to prostatic trouble. The case was discussed at some length in this department of THE JOURNAL, Oct. 3, 1936, page 1150. Perhaps it was because of this government action that the Electro Thermal Company changed its name for in August 1941 the Commission ordered the Thermalaid Method Inc., the trade style now used and its president, Charles H. McFarland of Steubenville, to discontinue the following misrepresentations in the advertising of their device: that the use of the Thermalaid will prolong the vigorous years of one's life and recuperate one's vitality or sex virility, provide a cure or remedy for prostatic gland disorders or offer any relief from prostatic disorders besides what might result from the local application of heat in cases of acute or chronic prostatitis in its milder forms. (The original Electro Thermal Company was once reported to be run by a John G. Homan who branched out into other fields of quackery. A Post Office fraud order which closed the mails to his rupture cure outfit, the 'New Science Institute' was dealt with in this department of THE JOURNAL, Nov. 16, 1935, page 1625.)

**Trox Tablets**—In September 1941 the Federal Trade Commission ordered W. S. and G. L. McClymonds, formerly known as Oxol Laboratories, Denver, to discontinue the following misrepresentations in the sale of this product: that Trox Tablets constitute a cure or remedy for various diseases and ailments of the kidneys and the prostate gland or possess any therapeutic value in the treatment of such conditions. In THE JOURNAL, Nov. 11, 1939, page 1828, a case was reported in which the Food and Drug Administration had declared Trox Tablets put out by Oxol Laboratories, Denver, to be fraudulently represented on the labels as effective for urinary infections, cystitis, prostatic and venereal disorders in violation of the Food and Drugs Act. In this connection government chemists had reported that the product was essentially a mixture of charcoal, starch, magnesium carbonate, extracts of plant materials, containing saponins and a small amount of oxyquinoline sulfate.

**Vibratherm**—The Vitaphore Appliances Inc., South Bend, Ind., signed a stipulation with the Federal Trade Commission in January 1938 in which it promised to cease representing that the Vibratherm produces a tonic effect on the entire nervous system immediately, also that it gives almost immediate relief to sufferers from prostatic disorders, is a competent remedy for constipation and relieves hemorrhoids. In April 1941 the Commission definitely ordered this concern to cease representing that the Vibratherm is a cure or remedy for prostatitis or is of any value in that condition in excess of giving temporary relief from symptoms of pain or that the use of this device is a remedy for bladder weakness, backache, headache, limb pains or nervousness or that it has any value in the treatment of hemorrhoids, constipation, sexual decline or women's disorders.

**Vitale Instantaneous Hair Dye**—This product put out by Castmire Mujojo trading as Alvi Inc. and Alvi Company, New York, was also known as Vitale Hair Coloring, Vitale Rapid Hair Coloring, Vitale Rapid Vitale Hair Dye and simply as Vitale. In August 1941 the Federal Trade Commission ordered Mujojo to discontinue advertisements which represent that this product is a safe or scientific one and free from harmful, injurious or dangerous chemicals, that its use will end prematurely gray hair or produce a permanent natural uniform shade or give the warmth, color, luster or glint of youth to the hair and also to discontinue advertisements which fail to carry conspicuously the caution that the product contains ingredients which may cause skin irritation in certain individuals, that preliminary tests described in accompanying directions should first be made and that to use the preparation for dyeing the eyelashes or eyebrows may cause blindness. Mujojo was permitted however to limit this warning in the advertisements to the statement: CAUTION: Use only as directed on label, if and when such label bears the first described caution conspicuously displayed and the accompanying labeling gives adequate instructions for such tests before each application.

**Witol Cosmetics**—These include Witol's New Liquid Skin Peel and Take Off. In May 1941 the Federal Trade Commission ordered Witol Inc. and its president, William Witol, as well as Witol Beauty Laboratories Inc., New York, to discontinue advertisements which represent that these two products will remove the outer layer of the skin and give the user a new, fresh surface skin, that these are effective in treating pimples, blackheads, whiteheads, freckles or superficial blemishes or will cause large pores or fine lines to diminish.

**Woodbury's Cosmetics**—In November 1933 the Jergens Woodbury Sales Corporation, Cincinnati, signed a stipulation with the Federal Trade Commission in which it agreed to cease representing that its facial creams constitute a new or unique protection from the danger of blemishes or will give the skin the care that makes beauty safe or change aging dryness to supple youth. That Element 576 directly gives the skin vital energy or such energy as vitamins in foods bring to the body or that Element 576 in Woodbury's Cold Cream causes the oil glands beneath the skin's outer surface to function better. In September 1941 the Commission ordered the Jergens Woodbury Sales Corporation, Cincinnati, to discontinue the following misrepresentations in the sale of a facial soap, a facial powder, a cleansing cream, a facial cream, a cold cream and a skin use cream: that the powder and cold cream are a skin and perm guard both before use and continuously during use, that they will guard the skin against blemishes, prevent infections from germs and kill germs under conditions of normal use, that the powder will spread farther than competitive products, that the presence of vitamin D in the creams will help users fulfil their fondles for beauty and that the vitamin D present in the soap will benefit the skin.

## SULFONAMIDE DERIVATIVES AND BACTERIAL CONTAMINATION OF STORED PLASMA

To the Editor—In THE JOURNAL, February 14, appeared an article by Dr Milan Novak entitled "The Use of Sulfonamide Derivatives as a Solution to the Problem of Bacterial Contamination in Stored Plasma"

or serum, with and without the drug, were inoculated with less than 20 bacteria per cubic centimeter and then held at 37 C, 22 C and 6 C. The highest temperature was used to simulate summer room temperature. Subcultures of 1 cc were made at intervals of three, ten and twenty-two or thirty days in semisolid agar containing para-aminobenzoic acid. In certain instances dilutions were made before cultures were taken. Some plate counts were also made of the motile bacteria. However, plate culturing alone, which was apparently used by Dr Novak, was found inadequate, for certain bacteria after having been in contact with the drug would not start growing for several days, during which time the plate became too dry to support growth,

In view of the present interest in human plasma for use in both military and civilian medicine, Dr Novak's report will attract widespread attention. Particularly is this true since so many laboratories and clinics are eagerly awaiting methods which offer simplification of the complicated and exacting procedures required for safely processing plasma. My attention was called to this report by the author's results being at wide variance with other available data. Because of the urgency of the problem, Dr Margaret Pittman was assigned the task of checking Dr Novak's work as nearly as could be done from reading his report. Dr Pittman's report follows:

Two different experiments have been done, one with pooled liquid human plasma and the other with restored frozen and dried human serum. With each a concentration of 0.2 per cent sodium sulfathiazole was used. Tubes containing the plasma

hence no growth developed. The pooled liquid plasma was inoculated with Staphylococcus aureus, Pseudomonas aeruginosa (pyocyaneus), Bacillus subtilis and Streptococcus bovis (isolated from frozen and dried cow serum), the restored dried serum was inoculated with the first three species and Streptococcus viridans. The results are given in tables 1 and 2.

At 37 and 22 C the staphylococci rapidly multiplied in the presence of the drug in both the plasma and the serum, the rate of growth, however, was slower than in the control tubes. Nevertheless, at the end of twenty-two days 10<sup>4</sup> bacteria per cubic centimeter were counted in the plasma containing the drug at both temperatures. Contrasting results were obtained with P. aeruginosa in the liquid plasma and in the restored serum. In the liquid plasma with the drug at 37 and 22 C no bacteria were recovered, at 6 C they were recovered through the twenty-second day. In this instance Dr Novak's observations

were confirmed. However, in the restored serum with the drug there was rapid multiplication of this bacterium in the presence of the drug.

*B. subtilis* grew in both the plasma and the serum at 37 and 22 C but at 6 C it could not be recovered from the tubes with or without the drug after the third day. The tube of plasma plus the drug at 37 C was lost after the third day of culturing, and another tube was set up with plasma of the same lot but from another bottle. Bacteria could not be recovered from this tube while in the control tube there was luxuriant growth.

With *Str. bovis* in the plasma there was not the slightest indication of bacteriostasis, in fact there was some indication that the drug acted as a stimulant.

*Str. viridans* did not multiply in the restored serum with or without the drug but it was recovered in equal number from serum containing the drug and from the control tubes over the same time interval.

An additional experiment was made with pooled citrated blood. Concentrations of 0.02 and 0.2 per cent sodium sulfathiazole were used. The bacteria added were *Staph. aureus* and *Str. bovis* used in the preceding experiments and a *Staphylococcus albus* isolated two days previously from human skin. The inoculated tubes were held at 5 C and cultured at different intervals up to seventy-two hours. At no time was there any significant difference in the number of bacteria recovered from the blood containing either amount of the drug as compared with the number from the blood containing no drug. The results obtained when 0.2 per cent of the drug was used are given in table 3.

Dr Pittman's report is not intended as a complete study of bacteriostatic or bactericidal influence of the sulfonamide drugs when dissolved in normal human plasma. However, using five different species of bacteria and one lot of pooled plasma and one of serum, and after exposing the bacteria to the drug-treated plasma or serum at three different temperature levels, and culturing three times during a period of approximately thirty days, she was unable to find any evidence that 0.2 per cent sodium sulfathiazole had an inhibiting effect to a degree to be of significance when used in processing plasma or serum. Since this study was undertaken Heath and Province (*THE JOURNAL*, March 28, p. 1034) have reported their observations, which confirm Pittman's results.

This study was repeated with whole blood in order to ascertain whether the action of sodium sulfathiazole would be different in the presence of the cellular elements of the blood. Here again the drug failed to exert any retarding action on the bacteria used and under the conditions of the test as described by Dr Pittman.

It is regrettable that Dr Novak should hold (paragraph 2 of his conclusions) that the addition of 0.2 per cent sodium sulfathiazole to the bleeding bottle is justification for indifferent technic in drawing blood or in recovering the plasma. Up until now there is no known acceptable bactericidal agent which will accomplish this. On the other hand, qualified technicians using the aseptic bleeding technic, followed by a closed system of processing the plasma, can produce a sterile product even on large scale production. This is being illustrated in the present program of collecting blood and processing it to the dried plasma for the armed forces. Operating under the minimum requirements specified by the National Institute of Health for licensed laboratories, one bleeding clinic (under Red Cross auspices) has, to date delivered 6,606 consecutive uncontaminated bleedings. Two processing laboratories which receive blood from this and seven other bleeding clinics have to date processed to the dried state 60,685 bleedings with a loss of 286 bleedings, or 0.47 per cent, because of contamination. Some bleeding clinics and processing laboratories where less regard is given to essential details have records less good. We have yet to find the easy short cut to preparing uncontaminated citrated normal human plasma.

National Institute of Health

## THROMBOSIS OF RENAL ARTERY SIMULATING CORONARY THROMBOSIS

*To the Editor*—In their paper "Thrombosis of Renal Artery Simulating Coronary Thrombosis" (*THE JOURNAL*, May 2, p. 27) Drs. Wolfe and Donnelly state "The clinical manifestations of renal artery thrombosis are as yet not well recognized."

There is no complete description, as far as we can find, in any textbook or periodical of the clinical manifestations of thrombosis of the renal artery. I should like to call their attention to a paper published by me in the *Archives of Internal Medicine* in April 1908 on "Clinical Manifestations of Hemorrhagic Renal Infarct." The clinical signs and symptoms of thrombosis of the renal artery are there described and discussed in great detail. In my study of the literature on the subject at that time I found descriptions of the syndrome characterized by that painstaking attention to physical signs so characteristic of the masters of the art of diagnosis of the era when urography was unknown. I have reference to the contributions on the subject by Traube, Leube, Senator, von Recklinghausen and particularly Rudolph Schmidt, who reported 3 cases from Neusser's clinic all of which he diagnosed ante mortem. I had the good fortune to study and to report the first case in English literature. The historical value of my case may be somewhat enhanced, at least to American readers, by the fact that my two consultants in the case each were outstanding figures, one in internal medicine, the other in surgery. I have reference to Bertram W. Sippy and John B. Murphy. Evarts Graham was the intern on the case. The gross specimens were presented to the Pathologic Museum of the Rush Medical College.

GEORGE HALPERIN, M.D., Chicago

## SULFANILAMIDE FAST GONOCOCCI

*To the Editor*—In an editorial in *THE JOURNAL*, May 2, "Sulfanilamide Fast Gonococci," the writer refers to the publications of Boak, Westphal, Carpenter, Bang, Mahoney and others. He concludes from the possibility of artificially fastening gonococcus strains to sulfanilamide or sulfapyridine, and the failure of attempts to fasten them to sulfathiazole, that "the failure of the gonococcus to develop resistance to sulfathiazole suggests that sulfathiazole fast strains are not likely to be developed in the clinic or to be spread to the general population."

The author apparently overlooked the recent publication of my associates and myself on the behavior of various gonococcus strains to sulfathiazole (Cohn, Alfred, Steer, Arthur, and Seijo, Irma. Correlation Between Clinical and In Vitro Reactions of Gonococcus Strains to Sulfathiazole, *Am J Hyg* 203:276 [Feb.] 1942). With the method described in the article we have been able to demonstrate the existence of gonococcus strains naturally resistant to sulfathiazole both in vitro and in vivo. There was a close correlation between the clinical response of the patient to the drug and the reaction of the strain to sulfathiazole in the test tube.

ALFRED COHN, M.D., New York

## ARMY NURSE CORPS

*To the Editor*—The story "The Army Nurse Corps" in the April 18 issue, page 1374, is incomplete. Women trained nurses entered the United States Army Medical Service in August 1898 at Montauk, N. Y. The deaths at the General Hospital where I was executive officer averaged fifteen a day. Nursing was our great need. Through Howard Townsend, Red Cross executive at Montauk, I asked President McKinley for these nurses. Authority was at once given. During the period left out in your article nurses served in the United States in the Philippines in Cuba and in Puerto Rico, also on the hospital ship *Relief*. It seems too bad that the pioneer nurses should not be given credit for the heroic work done then and since.

**Hospitals Liability for Electric Lamp Burn**—The plaintiff was admitted to the defendant hospital one morning preparatory to undergoing an operation. Sometime during the afternoon a hospital attendant attached an electric lamp and reflector to the bedstead at the foot of the plaintiff's bed. The lamp was attached by means of hooks similar to the ear bows of eye glasses. The operation was performed about 8 o'clock in the evening, under a spinal anesthetic, and the plaintiff was returned to his room an hour or so later. In the middle of the night the plaintiff complained of a burning sensation in his feet. When the bed clothes were removed a nurse discovered the lamp which had formerly been attached to the foot of the bed. The plaintiff's foot had been seriously burned. Subsequently the plaintiff sued the defendant hospital for damages on account of the injuries sustained as a result of the alleged negligence of the defendant's servants. The trial court refused to submit the case to the jury and dismissed the plaintiff's complaint, so the plaintiff appealed to the Court of Appeals of New York.

The defendant contended that the trial court ruled correctly in dismissing the complaint because the plaintiff had not produced sufficient evidence to warrant the submission of the case to the jury. It argued that the plaintiff had not negated the possibility that the burn was caused by his own negligence or that of some one for whose actions the defendant hospital was not responsible. It also insisted that there was no proof that the burns were caused by the lamp. The Court of Appeals said that circumstantial evidence was sufficient if it supported the inference of causation, even though it did not negative the existence of a remote possibility that the injury was not caused by the defendant. The plaintiff's evidence, said the court, was sufficient, if believed, to show that the plaintiff was not burned when he was put to bed after the operation, that he felt the burn later, that the lamp was removed from under the bed clothes and that the burn was of the kind which could be caused by the lamp in question. Furthermore, said the court, it was unreasonable to assume that some complete stranger, or even the plaintiff's physician, entered the plaintiff's room during the operation and tampered with the bed lamp. The court therefore concluded that the plaintiff's evidence negated all but the barest possibility that the defendant was free from negligence and held that the case should have been submitted to the jury. The court also held, although the defendant claimed no immunity because of its charitable nature, that it is now well settled in New York that even a charitable hospital is liable for the acts of its servants. Judgment for the defendant was accordingly reversed and a new trial granted.—*Dillon v Rockaway Beach Hospital & Dispensary*, 30 N E (2d) 373 (N Y, 1940)

**Medical Services Right of Court to Order Operation on Child**—Section 85 of the Domestic Relations Court Act of the city of New York provides that whenever a child within the jurisdiction of the court and "under the provisions of this act appears to the court to be in need of medical or surgical care a suitable order may be made for the treatment of such child in its home, in a hospital or other suitable institution." The child involved in this case, a 10 year old girl, suffered from a deformity of her right leg induced by poliomyelitis, and an operation to correct it was necessary. The mother desired that the operation be performed but the father refused his permission. On petition of the mother, the case came before the domestic relations court of the city of New York, children's court, Kings County.

It was doubtful, the court said, whether under the common law a court had the power to order treatment for children to the extent of even a surgical operation or to require that parents do that which is promotive of the interests and is protective of the rights of a child. There has been an emergence from that period in the history of man and its prejudice

and limitations of a community interest in the child population have been left behind. The law is a growth, otherwise it could not serve the purposes of man and his needs. Like life, the law constantly undergoes change. Law is instituted among men for the protection of the individual against the community as well as for the protection of the community against the individual. It also protects children against parents when there is neglect. The physical well being of children is the basis for the moral care, proper training and guidance. A child, the court pointed out, deprived of the use of its limb and the limb becoming progressively worse cannot have a sense of security. It feels itself different from others. It suffers from a sense of rejection. It cannot take its proper place in the group in which it lives. To the extent that medical science can correct the deformity or the limitation of the use of the limb, that service should be accorded. When the legislature devolved on the court the power to make an order for surgical care, the court said, it cannot be said that an order is to be made only in a case in which the parents consent to such an order. The court may order an operation not only in an instance in which the life of the child is to be saved but also in instances in which the health, the limb, the person and the future of the child are at stake.

A report submitted to the court by the New York Orthopedic Hospital specifically stated that an operation was necessary to correct the deformity from which the child was suffering and which was becoming aggravated. Three physicians testified to the need for the operation. The father of the child testified in opposition to the operation. He gave no reason for his opposition. On all the testimony submitted there was no doubt in the mind of the court that a successful operation would correct the condition, and in the opinion of the court it was in the best interests of the child that the operation be performed. The court therefore entered an order accordingly.—*In re Rotkowitz*, 25 N Y S (2d) 624 (N Y 1941).

**Governmental Hospitals Liability for Negligence of Agent in Performance of Administrative Duties**—The plaintiff who was engaged as a nurse in the Bellevue Hospital at a salary of \$90 a month plus 'board, maintenance and proper medical and surgical attention' became ill while on duty and was sent to the nurses infirmary. To stop the vomiting and nausea from which she was suffering a physician prescribed hypodermic injections of Magendie's solution. Four injections in the upper part of her left arm were administered by various nurses on duty in the infirmary. In a few days her arm commenced to swell and became painful at the place at which the injections had been made. Although an operation, as well as numerous lancements was performed the plaintiff finally lost practically the entire use of the arm and hand. In a subsequent suit by the plaintiff against the city of New York, owner of the Bellevue Hospital, a public institution to recover damages for the injury sustained, a witness for the plaintiff testified that Magendie's solution is an aqueous solution of morphine sulfate and is subject to decomposition in three or four days. This witness further stated that when the solution is freshly prepared it is colorless but as it decomposes it changes to a yellowish brown and finally to dark brown. The plaintiff testified that the fourth injection put into her arm was of a brownish liquid. The evidence also showed that the hospital nurse supervisor had for at least six months before the plaintiff received the injections been aware of the state of decomposition of the solution and had pronounced it unfit for use. It was not destroyed, however, but was retained in the drug cabinet with the request by the supervisor that it not be used. From a subsequent judgment for the plaintiff in the trial court and its reversal by the supreme court, appellate division, the plaintiff appealed to the Court of Appeals of New York.

The defendant first contended that the plaintiff was not entitled to maintain this action against the city because her sole and exclusive remedy was under the workmen's compensation act. The Court of Appeals held, however, that the risk of the injury suffered by the plaintiff was not incidental to her employment as a nurse but was a risk to which any one receiving such treatment in a hospital would be subjected. Since the occurrence of the injury was not made more likely because of her employment, the injury did not arise out of

and in the course of employment and was, therefore, not subject to the provisions of the compensation act.

The defendant next contended that the negligence complained of was that of the nurse who administered the solution acting in her professional capacity rather than in the performance of a mere administrative act on behalf of the hospital. It was conceded that the doctrine of respondeat superior is not applicable between nurses engaged in professional tasks in the treatment of patients in a hospital, and their employer, yet if a hospital is negligent in the performance of an administrative function, it is liable in damages. The plaintiff did not contend that there was any negligence in the administration of the injection, she contended that the hospital was negligent in allowing decomposed medical supplies to be made available for use. The Court of Appeals said that among the administrative duties of a hospital was the providing of proper and necessary food and medicine. The court therefore held that the supervisor, having known for six months that the Magendie's solution was stale, was obligated to see that it was either removed or destroyed and a fresh solution supplied. Her failure in that respect, was a failure of the hospital in an administrative capacity for which the owners were liable.

Finally, the defendant contended that it was immune from liability because in the operation of the Bellevue Hospital it was exercising a governmental function. The Court of Appeals admitted that when a city furnishes medical and surgical treatment to those of its citizens who cannot afford to pay it is performing a governmental function. The infirmary in which the plaintiff was treated, however, was not operated for the benefit of the public, it was open only to nurses. Furthermore, the plaintiff was not a recipient of charity but was, in effect, a pay patient since part of her salary as a nurse in the Bellevue Hospital was "proper medical and surgical attention." The infirmary was therefore, maintained in the performance of a contractual duty and not as either a governmental obligation or a public health measure.

Accordingly the judgment of the appellate division was reversed and that of the trial court in favor of the plaintiff affirmed.—*Volk v City of New York*, 19 N Y S (2d) 53, 30 N E (2d) 596 (N Y 1940).

**Current Medical Literature****AMERICAN**

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1932 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints are a rule the property of authors and can be obtained for permanent possession only from them.

**Rheumatic Carditis in Tropical Country**—Carrillo encountered from April 1936 to April 1939 22 cases of rheumatic fever, chorea and endocarditis among 3,771 clinical records from the pediatric ward of the Hospital San Juan de Dios, at San José. Electrocardiograms were not made and it is possible that other cases were not noticed. The incidence of mitral stenosis in the last thousand necropsies performed at the hospital during the five years preceding May 1941 was 1.1 per cent. Climate alone should not be given undue importance in the etiology of rheumatic infection, as other factors may play a determining role in the evolution and the cardiac sequelae of the disease.

**Syphilitic Cardiovascular Disease**—The frequency with which syphilitic heart disease and bacterial endocarditis are associated was ascertained by Koletsky in reviewing 4,000 consecutive necropsies performed at the University Hospitals of Cleveland. The study revealed 5 cases with a diagnosis of cardiovascular syphilis and bacterial endocarditis. In four of these hearts stigmas of rheumatic fever were also present, and in at least two there was a combined syphilitic and rheumatic lesion of the aortic valve. In the fifth case syphilis was confined to the root of the aorta, and the acute bacterial endocarditis was apparently superimposed on a normal aortic valve. These observations do not support the belief that syphilis is a significant predisposing factor in bacterial endocarditis.

**Sulfanilamide in Acute Glomerular Nephritis**—Williams and his associates compared the course of acute hemorrhagic nephritis in 42 patients treated with sulfanilamide and 108 patients similarly treated but not given the drug. In the subjects receiving sulfanilamide foci of infection cleared up more rapidly, signs of renal damage disappeared more rapidly, the nephritic exacerbations following tonsillectomy occurred less frequently, the duration of edema and hypertension was shorter and the incidence of clinical recovery was greater. One of the 42 patients treated with sulfanilamide died in the acute stage of the disease. Recovery was complete in 15 of the 33 who returned for observation after six months and in 29 of the 39 followed for at least two years. Three other patients followed for only a few weeks are in a quiescent stage. Five of the 39 patients are in the quiescent stage and 2 are in a progressive stage. Conversely there were 12 deaths during the acute stage among the 108 patients and 5 deaths following a progression to chronic nephritis. Only 56 patients recovered completely, 11 are in the quiescent stage and 24 are in the chronic progressive stage of the disease. The immunologic reactions, as exemplified by the antistreptolysin titer of the blood serum, have been practically the same in the two groups of patients. There was no evidence that sulfanilamide caused renal damage.

**Cavity Healing and Bronchial Occlusion**—Pagel and Simmonds state that three anatomic forms of healed cavities can be differentiated at roentgen study or at necropsy: (1) the solid focus due to retention, inspissation and final calcification of the cavity contents, (2) the radiating scar and (3) the bronchiectatic area remaining after the caseous and tuberculous elements in the wall of the cavity are replaced by ordinary granulation tissue, with subsequent epithelization and fibrous shrinking of the space. Six examples of cavity healing by conversion of the space into a solid, caseous and calcified focus are presented. At necropsy no cavity could be traced but corresponding in shape, size and location there was a caseous nodule resembling an ordinary "round focus." Various stages of the development were represented by the 6 cases. Regarding the frequency of the three anatomic forms of cavity healing, the authors have encountered 11 of these, and only 2 of them presented healing of the wall of the cavity with persistent cavitation, while 9 were instances of cavity closure by conversion into a caseous or calcifying nodule. The frequency (16 cases) is approximately the same when the 33 cases (16 cases) reported in the literature are analyzed. This frequency of cavity healing by conversion into a

focus vindicates the assumption made by many clinicians that a calcified nodule often represents the last remnant of a healed cavity. Why some cavities heal by scar formation and others by conversion into a solid nodule is a matter of speculation. The following tentative explanation is advanced. In the authors' cases pneumothorax was the therapy used, following the operation there may be a rapid closure of the bronchus which has already been partially obstructed by crassation. The thick crassous lining of the cavity does not have time to be discharged or to become absorbed but absorption of the air in the cavity allows a collapse and the crassous lining appears as a solid encapsulated focus. When the bronchus is more patent drainage is more free and there is less material to form a solid nodule. The closure of the cavity also may then be a slower process and be accomplished by concentric shrinking of the wall of the cavity by fibrosis and obliteration of the lumen with final scar formation. Four weeks appears to be the minimum time required for cavities to heal.

**Biliary Tract Disease**—Wilensky has observed that the prognosis in obstruction of the common bile duct is favorable provided infection of the biliary tract does not set in. Once infection gains a foothold, whether the obstruction is relieved or not frequently the course is rapidly downhill. Subsequent operative release of the obstruction is often too late to reverse the preceding sequence of events. The resulting cholangiohepatitis does not appear to be due to any particular bacterial organism although it is probably derived from the alimentary canal. The quantitative extent to which the hepatic parenchyma is functionally involved will determine the final outcome but frequently there are no recognizable corresponding anatomic changes. Infection in the biliary radicals is not the only means of causing sufficient hepatic damage to produce the terminal picture, for direct trauma with pulpification of the liver and other mechanisms have produced the liver-kidney syndrome. In his cases the characteristic changes were degenerative alterations in the renal tubules and at times in the glomeruli, with occasional hemorrhages in the renal parenchyma. He saw 1 patient with milary abscesses. Myocardial changes when present were also of a degenerative nature. A severe degree of periportal cellular necrosis of the liver was present in all cases.

**Treatment of Cancer of Tongue**—Richards considers the first essential step toward a better understanding of the general problem of the treatment of cancer of the tongue to be the adoption of some uniform classification which would at least bring into one group those patients for whom there is reasonable hope of cure. Of approximately 200 cases of cancer of the tongue that

he treated during the last ten years 167 have been analyzed in some detail and classified into four groups with primary lesions (according to size) and into three groups with secondary lesions (according to the extensiveness of the metastasis). In treating and handling cancer of the tongue the avoidance of traumatism is as essential as is asepsis in general surgery. The policy has been to complete the treatment of the primary lesion before the secondary involvement if such is present, is treated, usually by neck dissections if the primary lesion can be or is likely to be controlled. When neck dissection is not advisable, irradiation of secondary involvement has been carried out concurrently with that of the primary lesion. When the diagnosis of a primary lesion has been verified and the mouth prepared by careful oral hygiene treatment is begun by external roentgen irradiation at 400 kilovolts or with the radium bomb containing 4 to 5 Gm of radium. With either of these forms of irradiation effective control of the lingual cancer can be secured provided tumor doses (5500 roentgens) are delivered to the entire tumorous area. Roentgen rays at this voltage appear somewhat more satisfactory than radium. The other factors employed are a composite filter equivalent to 6 mm of copper, with a half value layer of 4.5 to 5 mm of copper and an intensity of 7 to 10 roentgens per minute. The skin distance is 100 to 110 cm. The depth dose at 10 cm is 36 per cent. Each treatment represents a dose of 200 roentgens delivered in forty minutes. Allowing for individual variations, fully established tissue reactions will be reached at total doses of 2100 to 4500 roentgens per port in approximately four weeks. When about half of the external dose has been administered, the irradiation is supplemented by intraoral irradiation for which roentgen rays at 200 kilovolts through an intraoral cone at 43 cm distance are used. The daily dose from this source is 280 roentgens, and approximately 3,000 roentgens is delivered within two weeks. Thus the final tissue reaction produced in the tongue is the summation of the external and intraoral radiation, which should reach maximal intensity simultaneously. If after the tissue reaction has subsided completely all visible and palpable evidence of the primary lesion has disappeared, no further treatment is given. If there is evidence of residual disease, radium in reduced doses is applied by the interstitial method. Of 119 patients treated three or more years ago 37 per cent are living and are free from disease, 27 per cent are living and free from disease for five or more years. Palpable lymph nodes have never developed in 60 of these 119 patients. The three year survival rate for these 60 patients is 63.3 per cent and the five year rate is 49 per cent without recurrence to date. Clinically, of 19 patients with a primary lesion in stage 1 all were controlled, of 78 with stage 2 lesions 67, or 78 per cent, were controlled, of 67 with stage 3 lesions 40 or 54 per cent were controlled, and of 27 with stage 4 lesions 4 or 13 per cent, were controlled.

**Radioactive Phosphorus for Lymphosarcoma**—Kenney and his collaborators administered tracer doses of radioactive phosphorus to 18 patients with lymphosarcoma. From one to thirty-one days later a lymph node was excised from each patient and its radioactivity was measured and corrected for decay to the date of administration of the radioactive phosphorus. The average lymph node invaded by lymphosarcoma had a differential absorption ratio of about 3. Application of suitable formulas for estimating the amount of radiation that might be delivered to such tissue indicated that radioactive phosphorus might be a useful therapeutic agent for this disease. Courses of 70 to 100 microcuries of radioactive phosphorus per kilogram of body weight were administered in divided doses every seven to fourteen days. Of the 18 patients who have been or are being treated 5 have had complete regression or all evidence of disease and have been free from recurrence for one to eight months. 1 patient has had complete regression in one area and more than a 50 per cent regression in the other area, 1 had a good initial regression followed by rapid recurrence, 1 did not respond to the therapy and 1 died during treatment. The 9 remaining patients are still under treatment. The tissue most liable to early and serious damage from radioactive phosphorus therapy is bone marrow, but damage should be preventable by frequent blood counts and marrow aspirations and compared during the course of treatment. Serious damage

(marrow aplasia) to the bone marrow of 1 patient has been encountered and in 2 moderate anemia followed the administration of the isotope, but the blood picture improved after treatment was withdrawn.

**Hemorrhage from Gastritis**—The evidence for bleeding from gastritis is considered by Benedict from the pathologic, clinical, roentgen and gastroscopic points of view. Before 1933 the diagnosis of gastritis with hemorrhage was rare. Only 4 such cases are listed in the records of the Massachusetts General Hospital. In 3 of the cases the diagnosis was presumptive and in 1 it was suggested by roentgen examination and proved at operation. Since 1933, with the use of the flexible gastroscope, a positive diagnosis of hemorrhage from gastritis has been made in 42 cases. Although a positive roentgen diagnosis was made in only 3, it was suggested in 6 others. The superficial character of the erosions or ulcerations seen by gastroscopy makes them particularly difficult to demonstrate roentgenologically. In addition to the 42 cases there are records of 24 cases of gastritis and hemorrhage in which the question of ulcer was also raised. In the 5 cases with roentgen evidence of a healed duodenal ulcer at the time of the hemorrhage the bleeding evidently was from gastritis alone, as bleeding does not occur from a healed ulcer. In 9, previous or subsequent roentgen examination revealed a duodenal deformity without a crater or a duodenal ulcer. In 10 cases there was a positive roentgen diagnosis of duodenal or gastric ulcer at the time of the bleeding. Since gastroscopic study disclosed gastritis in all these cases it is more than likely that at least some of the hemorrhage was from the gastritis. In addition to the 66 cases of gastritis with hemorrhage, gastroscopy or esophagoscopy has revealed gastritis in the region of the hernia in 4 cases of hiatus hernia with bleeding. Also in 1 case of gastric varices, 1 of scurvy, 1 of chronic thrombocytopenic purpura and 1 of familial hemorrhagic telangiectases, all with hematemesis or melena, chronic gastritis was demonstrated by gastroscopy.

**Postabortional Sepsis**—From July 1938 through July 1941 Rebbbeck used ultraviolet irradiation of autotransfused blood as an adjunct to surgical intervention in the preoperative treatment of 17 and the postoperative treatment of 4 patients with post-abortional sepsis. Nine patients admitted instrumentation to produce abortion, 2 admitted taking medication, 8 had apparently spontaneous abortions, 1 patient with psychosis was treated after a therapeutic abortion because of apparent sepsis and 1

used medication and instrumentation. Ten patients were in a state of advanced infection on admission and 11 had early to moderately advanced infection. The pathologic condition ranged from simple, uncomplicated, acute septic endometritis to acute salpingitis, bilateral, "frozen" pelvis, pelvic abscess and septicemia. Following preoperative irradiation of the blood, infection did not spread. The 4 patients treated postoperatively were promptly relieved of toxemia, and their fever decreased. The temperature and toxemia of these 4 patients increased after operation and they were treated postoperatively because of apparent acute endometritis. The other patients had no significant rise of temperature, although their blood was irradiated immediately or up to nineteen days before operation. The results strongly indicate the preventive value of irradiating autotransfused blood. The patients were discharged from four to eight days after curettage.

**Acute Appendicitis in Children**—Allen reports a mortality of only 17 per cent (five deaths) among 293 children with acute appendicitis. He attributes the reduced mortality rate to earlier hospitalization, the use of fewer cathartics, more preoperative care aimed at correcting fluid balance (especially in the presence of toxic dehydration with spreading peritonitis), better anesthesia and the use of the McBurney incision. This incision is likewise believed to have been the chief factor in reducing hospitalization to fifteen and six-tenths days. Follow-up observation of cases in which drainage was employed and in which only the peritoneum was sutured reveals a decreased incidence of hernia.

**Fractional Spinal Anesthesia**—Ansbro and Pico employed the continuous spinal anesthesia developed by Lemmon in one hundred and five surgical interventions ranging from a radical mastectomy taking three hours and requiring 1,020 mg of procaine hydrochloride to removal of a fibroma taking twelve minutes and requiring 30 mg of the drug. The author believes that the term "fractional spinal anesthesia" would be more accurate than "continuous." Continuous suggests a long period of time, whereas the method is adaptable to the shortest as well as the longest surgical procedure. It is an unquestioned procedure in other types of anesthesia to give a sufficient amount of the drug to produce the desired depth of anesthesia, and it is logical that the fractional dose should be used in spinal anesthesia. The drop in blood pressure under continuous spinal anesthesia is notably less than with other methods of spinal anesthesia. This is probably due to the small amount of solution injected into the subarachnoid space at any one time. If alarming toxic symptoms should follow the injection of the drug with the fractional technique, 3 to 6 cc of cerebrospinal fluid can be withdrawn and it has been noticed that the nerves recover promptly from the anesthesia. Headache occurred in only 2 cases. There was no infection of the skin, muscles or meninges, although in 1 case fecal material had collected about the needle and remained there for two hours as the result of the spilling of intestinal contents through a colostomy under the surgical drapes. The incidence of urinary retention was 4 and of pulmonary atelectasis 3 per cent. There was no transient palsy, permanent paralysis or vertebral arthritis. The immediate operative mortality among 15,652 administrations of spinal anesthesia in eighteen American hospitals was forty deaths, or about 1/500.

**Subdural Hygroma**—In 3 cases of head injury with prolonged periods of unconsciousness, Scott found and drained much clear subdural fluid. In 1 of these the elastic type of xanthochromic subdural cyst was found. Consciousness in the 3 cases returned after the drainage. The subdural hygroma produced symptoms identical to those of subdural hematoma. The lesion should be suspected whenever a person with an injury to the head does not tend to recover after the usual proper measures for relief of intracranial pressure and evacuation have been carried out. The treatment is similar to that used for liquid subdural hematomas. An exploratory trephine or Hudson burr opening is made, the dura is opened, the subdural fluid is evacuated and the space is drained for twenty to forty-eight hours with a small cigaret drain. If there is an excess of fluid on the suspected side or relief is not obtained by drainage in three to five days, the opposite side should be inspected.

**Tuberculosis and Suppuration**—Baum and Amberson encountered pneumonia one hundred and two times in 97 tuberculous patients, fifty-five pulmonary abscesses with suppurative pneumonia in 54 patients who ultimately showed tuberculosis and 32 patients with bronchiectasis and tuberculosis. Pneumonia in the tuberculous population has potentialities of activating the tuberculous lesion. Suppuration within a pneumonic area is the most important factor in the subsequent activation of the lesion. Such suppuration frequently complicates pneumonia caused by the type III pneumococcus and is usually present to some degree in infection caused by the hemolytic streptococcus and other invaders of the interstitial tissue. The bronchorrhea and local hyperemia of pneumonia are factors that also may play an important part in activating a tuberculous lesion. The fibrocalcific lesion and the lesion successfully controlled by collapse therapy are the least likely to be activated by pneumonia. Suppurative pulmonary lesions, such as pulmonary abscess, gangrene and initially suppurative pneumonia, frequently coexist with pulmonary tuberculosis. The course of pulmonary tuberculosis is affected adversely by the complicating nontuberculous suppurative lesion. Tuberculosis may be superimposed on a preexisting suppurative lesion and on bronchiectasis. The activation of tuberculosis by a suppurative disease usually depends on the local destructive process, which disrupts the capsule, if any, and breaks down the tuberculous focus. Tuberculosis, once it develops in bronchiectasis, is likely to progress by being disseminated by copious purulent discharges and hemorrhage, but it may be arrested by collapse therapy. Suppuration in bronchiectasis favors progression of the tuberculosis, particularly if the latter is established in a bronchiectatic lobe.

**Chemotherapy of Tuberculosis**—Two patients with minimal, 1 with moderate and 10 with far advanced tuberculosis were given massive doses of sulfanilamide by the intravenous drip method. Several patients had extrapulmonary foci. In judging the results, Zucker and his colleagues evaluated the outcome in each case on the basis of the expected future course of the disease on bed rest alone. A time limit for therapeutic efficacy was set at about two months after completion of treatment. At the end of the five day period of intravenous sulfanilamide most of the patients were given small to moderate doses of sulfanilamide by mouth for from one to five days. Nine of the 13 patients received only one five day course of treatment, 2 received two courses and 2 received three courses. The interval between courses varied from three weeks to three and a half months. Only those patients were retreated who tolerated the therapy well and whose disease indicated that some benefit might be expected. Five of the treated patients showed no clinical change, 3 improved slightly, 4 showed continued progression of the disease and 1 patient with disseminated hematogenous tuberculosis, whose prognosis prior to chemotherapy was considered hopeless, died. The sputum of no 1 patient was permanently or completely converted from positive to negative. The sputum of 1 patient with minimal tuberculosis became negative immediately after the first course of treatment, as did the gastric content on two occasions, but four months later, while the patient was on a semiambulant regimen, the sputum was again positive. No beneficial or adverse effect on the pulmonary

tuberculosis was observed that could be attributed to chemotherapy. Effective chemotherapy in pulmonary tuberculosis would probably be most successful in patients in good general health and with early, exudative lesions. If a sufficient amount of a drug was to be given to such a patient and rapid improvement was not obtained, then it could be said that the drug lacked any specific effect. Of the 3 patients who showed some improvement, 2 with minimal pulmonary tuberculosis received two courses of treatment and showed slight resorption over a period of two and a half months and four months, respectively. In neither instance was the improvement better than could be expected on bed rest alone. The third patient after three courses of sulfanilamide had some resorption of infiltrate in both apices after six months and complete healing of a tuberculous pharyngeal ulcer in three months.

**Vitamin D in Treatment of Infectious Arthritis**—Slocumb states that large doses of vitamin D have partially controlled the symptoms of infectious rheumatoid or atrophic arthritis in 7 of 14 cases in which twenty-five courses of treatment (daily dose from 52,500 to 386,000 units for twelve days to fifteen and a half months) were administered. If there was no immediate clinical improvement the administration of the vitamin was continued for at least one and a half months. There was little objective effect. The beneficial effects were only transitory, as the symptoms usually recurred after treatment was discontinued. There was some risk of renal damage. However, the occurrence of toxic symptoms or renal damage was not necessary for clinical improvement to ensue. There was no definite correlation between the clinical improvement and toxic symptoms or renal damage and retention of urea. Gastrointestinal upset was the most frequent warning sign of toxicity, though in 1 case the urea became elevated without any gastrointestinal upset.

**Carbon Disulfide Absorption and Intoxication**—Braceland discusses the mental symptoms of carbon disulfide psychosis occurring in 8 of 120 workers in a viscose rayon plant and in 9 similar cases discovered in mental hospitals. The psychosis was characterized by confusion, combativeness, hallucinations, delusions, depression and, finally, amnesia for the acute attack. While the onset of the psychosis is usually acute, attentive observers have noticed a gradual personality change accompanied by a phase of irritability, depression, headache and insomnia. The libido is lessened, and dreams of a terrifying nature occur. The symptoms are not dependent on physical habitus or heavy exposure but to individual susceptibility to carbon disulfide. Once an individual has shown toxic symptoms, he should be removed from further exposure. A diet rich in vitamins should be procurable in the cafeterias of plants and the homes of workers employed by the carbon disulfide industry. Recovery takes from two to six months or more.

**Sulfanilamide for Erysipelas**—From April 1937 to August 1939 Siegel and his co-workers state that the 303 patients with erysipelas who entered the Los Angeles County Hospital were treated with sulfanilamide. The average number of days of illness before admission was two and six-tenths. The precipitating factor in 37 per cent was trauma, furunculosis and ulceration. The ages of the patients ranged from less than 1 year to 65 years. On admission 153 patients had one or more

associated diseases. The dose of sulfanilamide for patients up to 5 years of age was 0.065 Gm per pound of body weight for twenty-four hours. Half of the total dose was given at once and the other half was given in divided doses every four hours over the remaining twenty-four hours. After twenty-four hours the initial dose was reduced by one third and on the third day to one half. This maintenance dose was given for three to five days after clinical cure ensued to prevent relapse. Older children and adults were given similar treatment except that the dose was calculated at 1 Gm for 20 pounds (9 Kg) of body weight for twenty-four hours. The average sulfanilamide level in the blood of 121 patients determined forty-eight or more hours after admission was 5.8 mg per hundred cubic centimeters. The general average period of hospitalization was eight days, the general average time required for the temperature to reach normal was forty-eight hours and the general average time required for the lesion to regress was fifty hours. The lesion did not spread after treatment was instituted, and there was only one recurrence. Eight patients had complicating abscesses, 1 pneumonia with hemolytic staphylococcus septicemia and pulmonary abscess and 1 nephritis with uremia. The mortality rate for the hospital from 1929 to 1933 was 32.9 per cent for infants less than 1 year of age, and the average mortality rate was 8.1 per cent. There were four deaths among the 303 patients treated with sulfanilamide, or a gross mortality rate of 1.3 per cent. Two and possibly three of the four deaths were due to the drug, however, the consistently reduced morbidity and mortality from erysipelas that use of the drug brings about by far exceeds the dangers.

**Sulfadiazine and Sodium Sulfadiazine**—Wheeler and Plummer determined the absorption, excretion and acetylation of sulfadiazine orally and of sodium sulfadiazine orally and intravenously in 218 cases in which the drugs were administered over long periods of time. Sulfadiazine given orally yielded higher concentrations but smaller proportions of acetylated drug in the blood and in the urine than did any of the other sulfonamide drugs. Sodium sulfadiazine after oral administration yielded even higher concentrations of drug in the blood than did sulfadiazine and, like the latter, it acetylated to only a slight degree in the blood and in the urine. Initial doses of 4 Gm of sulfadiazine and of sodium sulfadiazine were much more effective than initial doses of 2 Gm in establishing a high concentration of the drug in the blood soon after treatment was begun. Sodium sulfadiazine given intravenously yielded a high level of the drug in the blood, it acetylated to only a slight degree and it appeared to be relatively nontoxic. Toxic reactions after sulfadiazine were less frequent and less serious than after any of the other sulfonamide drugs. Pharmacologically, this suggests that sulfadiazine and sodium sulfadiazine possess definite advantages over the other generally used sulfonamide drugs.

**Advantages and Uses of Desiccated Plasma**—Muirhead and Hill emphasize the importance of producing a large volume of desiccated plasma and report the experience they have gained from its clinical use in 276 cases in a routine hospital service during twenty-one months. A total of six hundred and seventy-four doses of four times concentrated plasma ranging from 50 to 7,690 cc per dose have been given. Only five febrile reactions, all of the pyrogenic type, were encountered. The disorders for which the plasma was given were shock, shock prevention, burns, protein feeding, edemas, head injuries, toxemias of pregnancy and other conditions. Distinctions between plasma and serum as a therapeutic agent can be disregarded, as the proper preparation of either gives an innocuous product. Adtevac or desiccated plasma is literally neither plasma nor serum. The use of Filter cel during Seitz filtration removes most of the fibrinogen fraction, leaving a plasma that approaches serum in composition. The main emphasis in the treatment of shock is to restore the circulating blood volume, prevention of exposure, warm surroundings and the giving of oxygen are of additional value. In military medicine one of the greatest problems is shock, and in this regard a therapeutic agent of high efficiency having ideal storage properties is essential. Properly desiccated plasma appears to be such an agent. For mass production bulk desiccation, first mentioned by Elser, is safe and can be easily performed.

**Specific Treatment of Staphylococcic Septicemia**—Julianelle has given specific antibacterial serum (obtained from rabbits following immunization with intact organisms treated with solution of formaldehyde, particularly prepared to contain high titers of antibody capable of reacting with the somatic carbohydrate extractable from pathogenic [type A] staphylococci) to 98 unselected patients with genuine staphylococcic septicemia and 4 with severe infection and unverified septicemia. All the patients received whatever supplementary treatment was indicated. Osteomyelitis was the most frequent forerunner of septicemia and responded best to serum, with a survival of 24 out of 27 patients. Fifteen patients had endocarditis, it was refractory to type A serum, and the fatality rate was 100 per cent. Of 14 patients with furunculosis and varying metastatic infection, 7 survived and 7 died. Of 8 patients with septicemia secondary to primary pneumonia, 4 died and 4 survived. In comparison, of 22 patients with pneumonia secondary to a primary surface lesion 12 died and 10 survived. Four patients with cellulitis with metastasis and 4 with septicemia terminal to some other condition died. The 3 patients with pericarditis and the 3 with sinus thrombosis with secondary meningitis died, whereas 3 with primary meningitis and 2 with endometritis following abortion survived. Of the remaining 19 patients with a variety of conditions, 8 recovered and 11 died. Staphylococcic septicemia in diabetes was encountered on five occasions. Although these 5 patients died there were other factors involved, so that the combination of diseases need not necessarily imply a fatal termination. Of the 54 patients who died, 15 did so within seventy-two hours after serotherapy was begun. The usual survival rate has been doubled, but the actual evaluation of the efficacy of the serum must await future work from different sources.

**Mastoidectomy Wounds**—Guerry and Putney used sulfathiazole locally in the simple mastoidectomy wounds of 20 unselected patients, while in 20 others, serving as controls the sulfathiazole was omitted. The drainage period of the patients whose wounds were treated locally averaged sixteen and seven tenths days, or 52.8 per cent less than that of the control series and the postoperative period of hospitalization was reduced to an average of eleven and four-tenths days, or 55 per cent. The use of sulfathiazole also enhanced healing and reduced suppuration to a minimum.

**Mammary Cancer in Rat**—According to Geschickter and Byrnes, a mammary cancer developed in 202 of 555 albino rats treated with estrogens. The animals were mated for 10 years, during which time spontaneous mammary cancer developed in a colony of more than 5,000 animals. The percentage of rats in which estrogenic mammary cancer develops varies but the disease might possibly develop in all of them.

were allowed to survive the required time but only a few animals with microscopic growths were allowed to survive. Only 2 such animals showed multiple metastases to the lungs and lymph nodes. To produce mammary cancer, the dose of estrogen must be well beyond the physiologic limit (ten or more times the threshold dose) and the treatment continuously applied for months. The production of mammary cancer is not influenced by the amount of the daily dose but by the duration of estrogenic activity and the method of administration. It is difficult to demonstrate that sex, age or castration influences susceptibility to estrogenic mammary cancer. Important species differences were evident in the experiments carried out in monkeys, rabbits and rats. The administration of testosterone or progesterone together with or following estrogenic stimulation does not prevent mammary cancer from appearing. However, the growth of estrogenic cancer is inhibited by anterior pituitary extract. Various changes in the endocrine glands make their appearance with mammary cancer and a cancerous change has been observed in other organs. Experiments on rats with atrophic and fibrotic mammary tissue suggest that mammary cancer in women may result from one or a combination of the following factors: (1) abnormally intense estrogenic stimulation during the mammary development of adolescence or during a previous pregnancy, (2) prolonged ovarian dysfunction during the menopause resulting in relative hyperestrogenism and having the characteristics of adenosis or Schimmelbusch's disease and (3) intense or continuous estrogenic stimulation during the menopause superimposed on the two foregoing factors.

**Antibody Level and Susceptibility to Influenza**—In an effort to determine whether there is a distinct correlation between a person's antibody level and his susceptibility to influenza A Hare and his colleagues carried out studies along these lines among an urban population. The subjects were asked to gargle 10 cc of isotonic solution of sodium chloride and eject it into a screw capped bottle for transport to the laboratory. Inoculation of ferrets was carried out as described by Hare and Yen and neutralization tests were carried out by the method described by Francis, Rickard and Beck. The immunity of the subject to influenza was ascertained by titration of the neutralizing antibody or the complement fixing antibody. The results suggest that there may be a correlation between the antibody level and the person's susceptibility to the disease. The investigation suggests that a high proportion of the normal population is susceptible to influenza A, for about 90 per cent have an antibody level which is at or below the highest level that is found before infection in persons who become infected. Attempts to raise this generally low level with the complex vaccine of Horsfall, Lennette and Rickard have not always proved successful nor does the immunity produced by one dose of the vaccine persist. A stronger vaccine, and possibly more than one dose, is therefore required to raise the titer in as many persons as possible with initially low titers. The most serious objection to mass immunization with vaccines of known

influenza virus is the fact that many influenzas, even during an epidemic, are due to agents as yet not identified. Therefore the isolation and identification of these other agents is a prime necessity before mass immunization is seriously contemplated.

**Gonococcal Infection**—Cox analyzed 500 consecutive men with gonorrhea admitted to the Boston Dispensary and treated with sulfathiazole. At the end of the second week following the beginning of treatment 453 patients were still under observation, of whom 296 (65 per cent) reached a cure status within two weeks. Exaggerated propaganda of this two week cure rate is not needed to convince the public that great advances have been made in the treatment of gonorrhea. The numbers cured in subsequent weeks (up to sixteen weeks) raised the total to 416. However, as an attempt is made to get a minimum of ten negative smears and cultures at weekly intervals before a patient is discharged as cured, only 234 of the 416 patients can be classified as cured. Some of the 36 men thought cured on the evidence of one or two negative cultures may have had a subsequent clinical relapse or positive culture, and also some of the 47 closed out before the end of the second week may have been actually cured. There is apparently no doubt that the 65 per cent two week cure rate can be attributed to sulfathiazole. The other patients may have been benefited by chemotherapy, but there is little justification for claiming a sulfonamide cure in a patient who did not reach such a status for six or more weeks after chemotherapy was begun. Sulfathiazole is the drug of choice at the moment, it is highly efficient and it is almost entirely free of toxic reactions. Because of the threat of war, an increase in genital infection is probable. Continued effort must be made to educate the public as to the dangers of infection, how the infection may be prevented and what to do if infection is suspected. Under no circumstances should the impression be allowed to prevail that gonorrhea is no longer a serious disease.

**Treatment of Influenzal Meningitis**—Alexander presents the data on 45 patients with influenzal meningitis who were given rabbit antiserum intrathecally and intravenously in conjunction with chemotherapy. The recovery rate was 74 per cent, or 33 patients. There is reason to believe that the amount of free specific polysaccharide in the blood and the spinal fluid is an index to the severity of the infection and together with the quantity of the same substance within the capsule of the organisms determines the amount of antibody necessary. Direct measurement is impossible. Only gross evaluation is possible on the basis of objective laboratory evidence. Increasing experience suggests that limiting the administration of serum by the intravenous route constitutes the method of choice. Rabbit antibody passes readily from the blood to the meninges (detected in the spinal fluid by the presence of agglutinins). While the evaluation of the size of the initial dose necessary for the total antibody needs of a given patient is in the experimental stage, certain criteria are of value. In mild cases of early meningitis in which examination of spinal fluid smears fails to reveal organisms but culture yields a growth in twelve to twenty-four hours, 50 mg seems to be sufficient. If the meningitis is moderately severe, if chemotherapy had been given for four to five days prior to the patient's admission to the hospital if the spinal fluid sugar is only slightly decreased and if organisms are difficult to find, approximately 75 mg seems adequate. If the meningitis is severe and no previous therapy had been given the patient, or if he has had chemotherapy for three to four weeks and the spinal fluid shows infection but the sugar is almost normal a minimum of 100 mg seems indicated. The

serum should be given intravenously for forty-eight hours and if at the end of this time the spinal fluid has not improved significantly and organisms are still demonstrable on smear, serum should then be administered intrathecally. Data on the 12 patients who died reveal that 3 were inadequately treated according to present criteria, 1 after apparent complete recovery for sixteen days continued to have leukopenia after the drug was discontinued and had a fulminating recurrence which failed to respond to therapy, 1 was improving and the spinal fluid became sterile for three days when leukopenia intervened, following which the course was rapidly downhill. Of the remaining 7 patients in whom leukopenia developed, 6 fall into the young infant group. The greatest problem is to improve the results in infants aged less than 7 months. It is chiefly a question of recognizing clinical evidence of meningeal involvement at an earlier stage, and for this the clinician must be depended on.
